This report provides results from stationary point count (SPC) coral reef fish and benthic habitat monitoring surveys conducted by the National Oceanic and Atmospheric Administration (NOAA) Pacific Islands Fisheries Science Center's Coral Reef Ecosystem Division in 2014. This includes the following regions: Northwestern Hawaiian Islands, Mariana Islands, and Wake Atoll in the Pacific Remote Island Areas.

## Acknowledgements

Thanks to all those onboard the NOAA ships *Hi'ialakai* and *Oscar Elton Sette* for their logistical and field support during the 2014 Pacific Reef Assessment and Monitoring Program (Pacific RAMP) research cruises and to the following divers for their assistance with data collection; Valerie Brown, Edmund Coccagna, Marie Ferguson, Louise Giuseffi, Tiffany Gutlay, Stephen Matadobra, James Morioka, and Tate Wester. We thank Rusty Brainard for his central role in developing and sustaining the Pacific RAMP, and the staff of NOAA PIFSC CRED for assistance in the field and data management. This work was funded by the NOAA Coral Reef Conservation Program, and the Pacific Islands Fisheries Science Center. Surveys conducted in the Northwestern Hawaiian Islands this year were led and funded by NOAA's Papahānaumokuākea Marine National Monument (PMNM).

Report template by A. Heenan, maps by P. Ayotte, figures and compiled by K. McCoy.

# Introduction

## Background

The Coral Reef Ecosystem Division (CRED) established a long-term monitoring program, known as the Pacific Reef Assessment and Monitoring Program (Pacific RAMP) in 2000. Pacific RAMP, which is supported by the National Oceanic and Atmospheric Administration's (NOAA) Coral Reef Conservation Program (CRCP), is tasked with documenting and understanding the status and trends of coral reef ecosystems in the U.S. Pacific. Pacific RAMP monitors reef areas in the following regions: the Hawaiian and Mariana Archipelagos, American Samoa, and the Pacific Remote Island Areas (PRIA), which include the atolls of Johnston and Wake and the U.S. Line and Phoenix Islands (Figure 1).

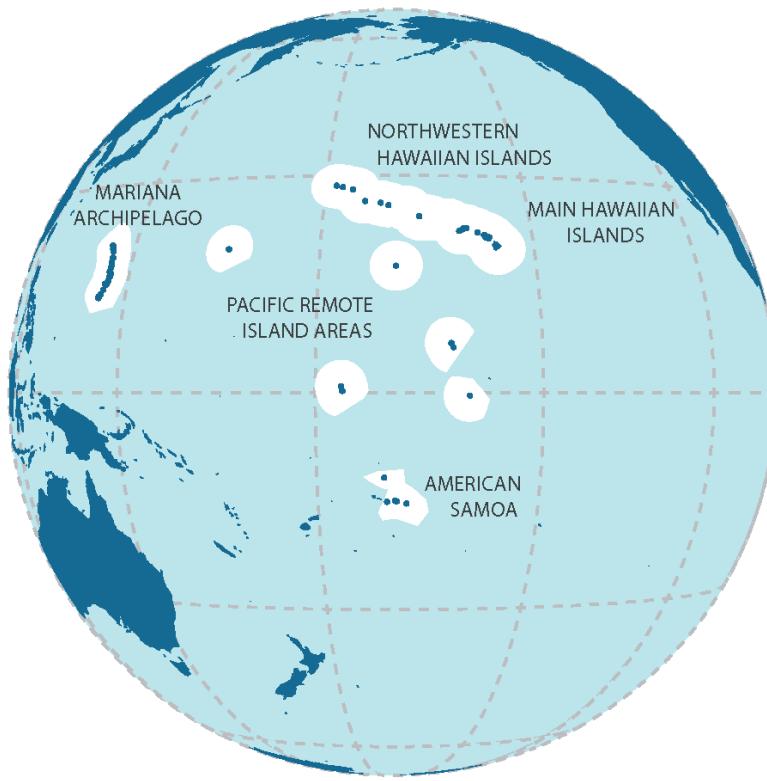

Figure 1 Coral reef areas surveyed by NOAA-CRED for Pacific RAMP. White areas represent the exclusive economic zones for each U.S. Pacific region surveyed.

Pacific RAMP involves interdisciplinary monitoring of oceanographic conditions and biological surveys of organisms associated primarily with hard-bottomed habitats in the 0–30 m depth range. From 2000–2011, regions were surveyed on a biennial basis and in 2012 Pacific RAMP changed to a triennial cycle, as part of the implementation of NOAA's National Coral Reef Monitoring Plan (NCRMP) that is funded by NOAA CRCP.

The NCRMP aims to support integrated, consistent and comparable monitoring of coral reefs across all U.S.-affiliated regions. Partnership and cooperation with other federal and jurisdictional management groups is a core principle of the

NCRMP and Pacific RAMP. For example, NOAA's Papahānaumokuākea Marine National Monument (PMNM) conducts a subset of coral reef monitoring surveys in the Northwestern Hawaiian Islands using a similar survey design and methods, and with considerable overlap in observers. Data gathered by PMNM is therefore readily merged with data gathered specifically for NCRMP by CRED. The supplemental data are included with data shown in this report.

The NCRMP has three themes: biological, climate and socioeconomic monitoring. Under the biological monitoring theme, the Pacific RAMP collects the following benthic and reef-associated fish data: fish and coral demographic information (species, size, abundance, biomass, disease (coral only), bleaching (coral only)); and information on benthic composition and key species (see [Appendix 1: Pacific RAMP data types collected for the biological theme of the NCRMP](#)). The focus of this report is the data collected using the stationary point count method (SPC) to survey the fish assemblage and rapid visual assessments of benthic composition (see [Section: Methods](#)). Additional, related fish and benthic data are collected via benthic transects and towed-diver surveys (for more information see NCRMP 2013); these data will be reported in a forthcoming series of complementary data reports.

## **Monitoring scope and historical programmatic changes**

Pacific RAMP includes the following biological monitoring objectives:

- Gather information on and document the status and trends of coral reef fishes and benthic assemblages in the U.S. Pacific;
- Provide information on status and trends of coral reef taxa of ecological and economic importance;
- Generate data suitable for tracking and assessing changes in reef assemblages in response to human, oceanographic, or environmental stressors; and
- Generate data suitable for evaluating the effectiveness of specific management strategies, and to support appropriate adaptive management.

These objectives are based on the key monitoring questions for NCRMP and the CRCP support for baseline observations and monitoring (refer to NOAA CRCP 2013 and NOAA CRCP 2009 for more details).

Pacific RAMP involves monitoring over very large spatial scales: ~40 islands and atolls spread over thousands of kilometers. The target of Pacific RAMP biological monitoring under NCRMP is to provide snapshot assessments of coral reef assemblages at U.S.-affiliated islands in the Pacific, with the core reporting unit being at the island level (or sub-island scale for some of the large islands), and as such the survey design and effort are optimized to generate data at the spatial scale of islands and atolls. The NCRMP is therefore explicitly a "wide-but-thin" survey program, with the aim of generating large-scale, regional status and trend information of the Nation's shallow water (0–30 m) coral reef ecosystems, in order to provide broad-scale context and perspective to local jurisdictions and other survey programs.

Additional surveys at smaller spatial scales that are intended to address more local information needs are also occasionally performed by CRED, but are not a part of Pacific RAMP. For instance, in September 2014 extra surveys were conducted in the Manell-Geus watershed in Guam as part of a NOAA Habitat Blueprint project, the results of which will be available in a forthcoming technical report.

In 2012, Pacific RAMP changed from surveying regions once every two years, to once every three years. The sampling design and methods used to monitor coral reef fish species and habitats for Pacific RAMP have also evolved over time.

More specifically, from 2000–2006 surveys were conducted at haphazardly located permanent sites using various belt transect methods. During 2007–2009, CRED and PMNM conducted comparative reef fish surveys using both the belt transect and the stationary point count (SPC) methods, and incorporated a stratified random sampling survey design. Survey replication (i.e., the number of sites sampled) greatly increased over this period and this higher level of replication has since been maintained ([Appendix 2: Surveys per region per year and method used](#)). Following this methods calibration period, from 2009 onwards the SPC method and depth-stratified random sampling were applied routinely in Pacific RAMP for surveying reef fish and associated benthic communities.

## Report structure

This report summarizes a subset of the reef fish and benthic survey data collected by the Coral Reef Ecosystem Division for Pacific RAMP and for compatible PMNM, National Marine Fisheries Service (NMFS) and CRCP survey missions in 2014. Over that time period, surveys were conducted in the following regions: the Pacific Remote Island Areas, the Mariana Archipelago, and the Northwestern Hawaiian Islands. The status of reefs in each region is first described in the wider Pacific context ([Section: U.S. Pacific reefs status](#)) and then at the island scale for each of the regions ([Section: Island status and trends](#)). Given the substantial changes in methods and design, this report specifically focuses on examining the observations collected since 2009, which only includes the subset of Pacific RAMP data that were collected using the SPC method under the depth-stratified random sampling design. In the final section, the publications that were produced in 2014 as a result of those surveys are listed; these publications either use the Pacific RAMP fish data or were co-authored by members of the CRED fish team and relevant to Pacific RAMP fish ecological monitoring work. All data used in this report along with other biological and climate-monitoring data collected by CRED for Pacific RAMP are available upon request (See [Contact us](#)).

## Methods

### Sampling domain and design

The target sampling domain for the SPC fish and benthic surveys is hardbottom habitat in water shallower than 30 m. All islands / atolls within regions are stratified by reef zone (backreef, fore reef, lagoon) and depth zone: shallow (0–6 m), mid (6–18 m), and deep (18–30 m). For the large majority of cases, entire islands or atolls are stratified by habitat and depth as described above, however, for populated large islands or where large portions of an island are under fundamentally different levels of management (e.g., inside or outside marine protected areas), there is an additional level of stratification based on “sector” (section of coastline and /or management status). Specifically, Guam is subdivided into three sectors: “Marine Preserve” (all areas within Guam’s Marine Preserve System); “Guam Open East” (areas outside of Marine Preserves on the east side of Guam); and “Guam West” ([Appendix 3: Sectors maps](#)). Furthermore, the generally larger, main Hawaiian Islands are divided into between 2 and 7 sectors per island, with sector boundaries designed to reflect broad differences in oceanographic exposure, reef structure, and local human population density ([Appendix 3: Sectors maps](#)). Finally, some of the smaller, more closely spaced islands are always pooled into single reporting and sampling units (i.e., Alamagan, Guguan and Sarigan in the Mariana Archipelago; Tutuila and Aunu'u, Ofu and Olosega in American Samoa; and Ni'ihau and Lehua in the main Hawaiian Islands). Due to their small size, these island groups are only ever allocated a limited number of sea days per cruise, and therefore total sampling effort

per island is inadequate to report data at the island level. Table 1 contains a summary of sampling terms and definitions, while details of the sectors and sampling effort on survey cruises covered by this report are given in [Appendix 4](#):

Term	Definition
Sample site data	The average values of estimated observed quantities from the SPC surveys conducted at each site. Typically derived from a single pair of simultaneous surveys. Sites are tied to geographic coordinates.
Reporting unit	A collection of sample sites, typically an island or atoll, and in some cases small island groups or sectors of larger islands.
Sampling domain	Hardbottom habitat in water less than 30 m depth.
Strata	Reef zone (backreef, forereef, lagoon) Depth zone (shallow 0–6 m <sup>1</sup> , mid 6–18 m, deep 18–30 m) Sectors (e.g., management units <sup>2</sup> and stretches of coastline with broadly similar habitat attributes and local human population density <sup>3</sup> ).

Table 1 Sampling terms and definitions.<sup>1</sup> For practical reasons, sites in which the centerpoint of the survey cylinder is shallower than 1.5 m are not surveyed.<sup>2</sup> For the island of Guam only.<sup>3</sup> Currently only in the main Hawaiian Islands and Guam.

## Site selection

Prior to each survey mission, sample site locations are randomly drawn from geographic information system (GIS) habitat and strata maps (Figure 2). That is, the latitude and longitude of site locations are randomly drawn from a map of the entire sampling domain.

Maps used in the site selection procedure were created using information from the NOAA National Centers for Coastal Ocean Science, reef zones (e.g., forereef) digitized from IKONOS satellite imagery or nautical charts, bathymetric data from the CRED-affiliated Pacific Islands Benthic Habitat Mapping Center, University of Hawai‘i at Mānoa, and prior knowledge gained from previous visits to survey locations.

During cruise planning, logistic and weather conditions factor into the allocation of monitoring effort around each island or atoll. Prior to the cruises, these constraints determine the area of target habitat from which sites are randomly selected; for instance, one side of an island may be deemed unsurveyable given seasonal wave conditions or CRED’s allocation of sea days aboard the NOAA research vessel may curtail the time spent in a particular area. The density of sites that are sampled per stratum is therefore determined by proportionally allocating effort (e.g., the number of sites to be surveyed) based on a weighting factor calculated from the area per stratum per reporting unit and the variance of the target output metrics (e.g., consumer group biomass and total fish biomass; see [Section: Fish groupings](#)), combined with what is feasible given the time constraints of ship time allotted per island or atoll.

During field operations on a research cruise, if a site is not suitable (e.g., soft- as opposed to hard-bottomed habitat) or accessible (e.g., due to inclement sea conditions), the dive is aborted and an alternate (backup) site is picked from the randomized list. In some cases, the spatial coverage of sampling sites around the entire area of target sampling domain is incomplete. As such, any inferences about coral reef fish assemblages and habitat made at the island-scale are clearly only representative of the areas surveyed ([Appendix 4](#)). For further details on the methods and maps used to select sites see Williams et al. (2011) or the Coral Reef Ecosystem Division Standard Operating Procedures: Data Collection for Rapid Ecological Assessment Fish Surveys (Ayotte et al. 2011).

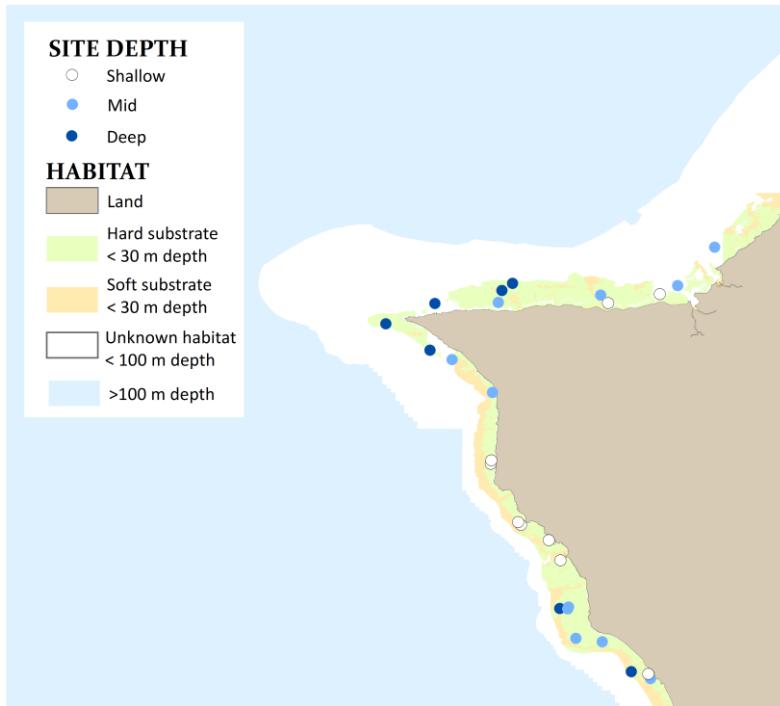

Figure 2 An example of the benthic habitat and depth strata information used in the site selection process. Reef fish survey sites are randomly selected within each depth stratum. Reef fish survey effort is allocated to optimize island-scale biomass estimates. Prior to surveying, a series of primary sites are selected, each circle identifies a site which falls on hard substrata (green) in the three depth strata (see map legend, shallow: 0–6 m, mid: 6–18 m and deep: 18–30 m). An alternate set of depth-stratified sites are also generated in the event that primary sites are not suitable or accessible.

## Sampling methods

At each reef fish survey site two types of data are collected, visual counts of the fish assemblage and surveys of the benthic habitat.

### Counting and sizing reef fishes

The SPC protocol closely follows that used by Ault and colleagues (Ault et al. 2006) and involves a pair of divers conducting simultaneous counts in adjacent, visually estimated 15-m-diameter cylindrical plots extending from the substrate to the limits of vertical visibility ([Figure 3](#)). Prior to beginning each SPC pair, a 30-m line is laid across the substratum. Markings at 7.5 m, 15 m and 22.5 m enable survey divers to locate the midpoint (7.5 m or 22.5 m) and two edges (0 m and 15 m; or 15 m and 30 m) of their survey plots. Each count consists of two components. The first of these

is a 5-min species enumeration period in which the diver records the taxa of all species observed within their cylinder. At the end of the 5-min period, divers begin the tallying portion of the count, in which they systematically work through their species listing and record the number and estimated size (total length, TL, to the nearest cm) of each individual fish. The tallying portion is conducted as a series of rapid visual sweeps of the plot, with one species-grouping counted per sweep. To the extent possible, divers remain at the center of their cylinders throughout the count. However, small, generally site-attached and semi-cryptic species, which tend to be underrepresented in counts made by an observer remaining in the center of a 7.5-m-radius cylinder, are left to the end of the tally period, at which time the observer swims through their plot area carefully searching for those species. In cases where a species is observed during the enumeration period but is not present in the cylinder during the tallying period, divers record their best estimates of size and number observed in the first encounter during the enumeration period and mark the data record as “noninstantaneous.” Surveys are not conducted if horizontal visibility is < 7.5 m, i.e., when observers cannot distinguish the edges of their cylinder (see Ayotte et al. 2011). Biomass per fish is then calculated using the standard length-weight equation. Data from the two adjacent SPC surveys are averaged to create a biomass estimate for each site ([Section: Data handling](#)), in cases where more than one SPC paired survey is conducted, data from matched members of each pair are first averaged before pair-specific results are averaged to create site estimates.

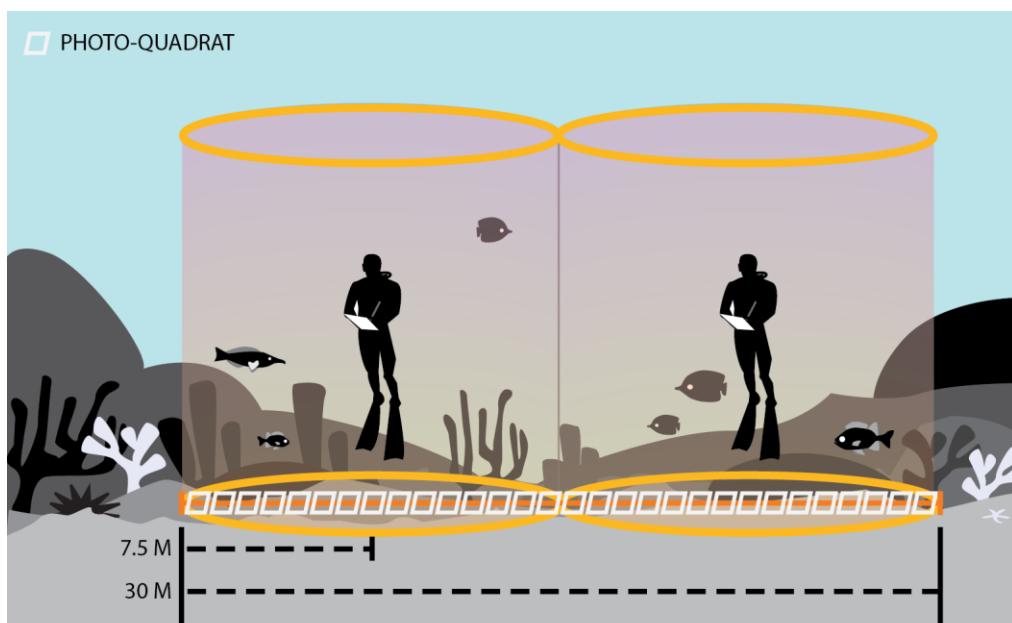

Figure 3 Side view of the stationary point count method. Dive partners count and size fishes within adjacent cylinders measuring 7.5 m in radius. Once the fish survey is complete, divers estimate benthic habitat composition and a benthic photo-transect is collected, spanning the two cylinders.

### Assessing benthic habitat characteristics

Two complementary methods are used to assess benthic composition within the same area where fish are surveyed. The first involves divers conducting a rapid visual assessment of the percentage cover of major functional categories of benthic cover and the second involves collecting photo-quadrat images of the benthos taken along the survey transect line that are later analyzed (Figure 3). The rapid visual assessment method provides a coarse but immediate estimate of benthic composition. In contrast, the photo-quadrat surveys provide estimates of benthic composition at a higher

taxonomic or functional resolution, but only after substantial post-survey data processing. As with the fish data, benthic data from the two adjacent SPC surveys are averaged to create an estimate per site.

### Benthic visual assessment

After completing the fish survey, both divers scan the benthos in their survey cylinder for 2–3 min and visually estimate the percentage cover of each of: encrusting algae, fleshy macro algae, hard coral, turf algae, sand and soft coral. Divers also estimate the slope, broad habitat type and structural complexity (Ayotte et al. 2011). Divers record reef habitat complexity by visually estimating the percentage of the cylinder that falls into the following levels of vertical relief: <0.20 m, 0.20–0.50 m, 0.50–1.00 m, 1.00–1.50 m, and >1.50 m. The abundance of free (e.g., *Tripneustes*, *Heterocentrotus*, *Diadema* and *Echinothrix*) and boring (e.g., *Echinometra* and *Echinostephus*) urchins is also rapidly visually assessed and recorded on a DACOR scale (Dominant, Abundant, Common, Occasional, Rare). Finally divers identify the broad-scale habitat type for the general area of the survey. The habitat classification scheme follows the geomorphological structures as identified by the Biogeography Branch of the NOAA National Ocean Service National Centers for Coastal Ocean Science. The coral reef and hardbottom habitat types are: aggregate reef, individual patch reef, aggregated patch reefs, spur and groove, pavement, pavement with sand channels, pavement with patch reefs, reef rubble, sand with scattered coral/rock and rock / boulder (Kendall and Poti 2011).

### Photo-quadrat survey

With the fish survey and rapid benthic visual assessment completed, one diver takes photographs of the benthos at 1 m intervals along the transect line (30 photographs per site) ([Figure 3](#)). A 1 meter PVC stick is used to position a digital camera (Canon PowerShot SD1200 IS, 10.0 megapixel) directly above the substrate to frame an area of ~0.7 m<sup>2</sup> per photograph. These images are archived for future analysis.

Our primary benthic assessment method is the photo-quadrat survey because it is a proven standard method that allows benthic composition to be identified to a higher resolution. However, due to a lag in analyzing the photo-images, only the visual assessment data are shown in this report and we do not use the rapid visual assessment to infer trends in benthic cover over time. Photo-quadrat data and benthic trends will be available in future reports.

### Data entry and storage

Data were entered into a Microsoft Access database. Upon completion of the monitoring cruise, all data were migrated to an Oracle database that is stored on a server at the Pacific Islands Fisheries Science Center.

### Data quality control

Data quality control is implemented at three main stages:

- Ongoing routine training of observers ([Figure 4 Pre-field](#), [Appendix 5: Quality control](#)).
- Checking for errors at the data entry stage ([Figure 4 In the field](#)). This occurs on the cruise when observers check the data entered by their dive partner against their datasheet for typing and potential sizing errors. At the

end of the cruise, a series of error checking scripts are run prior to migrating from the data entry database (Access) to the storage database (Oracle) (Figure 4 Post field).

- Examining diver estimation accuracy. This occurs during and after the monitoring cruise when diver estimates are compared between dive partner pairs (Figure 4 In the field). Observer comparisons from the regions surveyed in 2014 are in [Appendix 5.2](#) Observer cross-comparison.

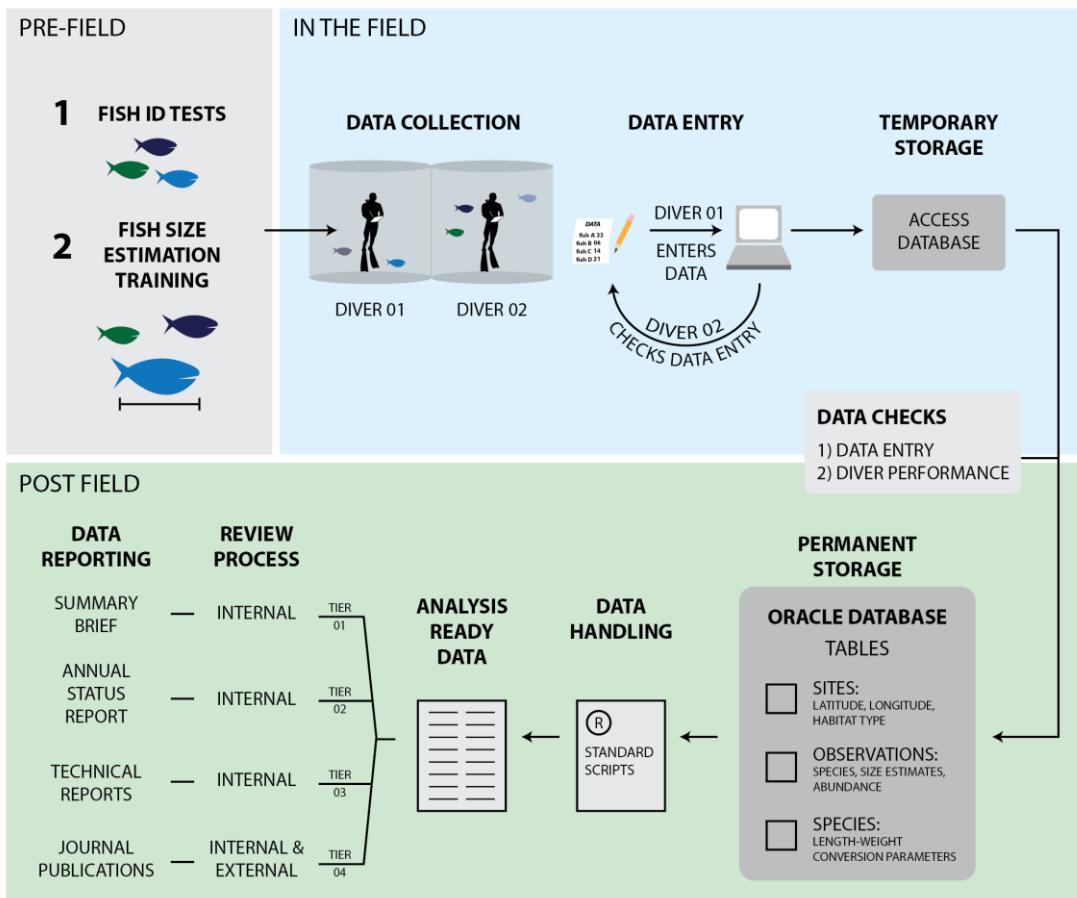

Figure 4 The training, data collection, data processing and reporting phases for Pacific RAMP fish and benthic surveys.

## Data handling

### Calculating fish biomass and benthic cover estimates per site

Using the count and size estimate data collected per observer in each replicate survey, the body weight of individual fish is calculated using length-to-weight (LW) conversion parameters, and, where necessary, length-length (LL) parameters (for example, to convert TL to fork length [FL] for species with LW parameters based on FL). LW and LL conversion parameters were taken from FishBase (Froese and Pauly 2010, Kulbicki et al. 2005; [Appendix 6: Species list](#)). Herein the term “biomass” refers to the aggregate body weight of a group of fishes per unit area ( $\text{g m}^{-2}$ ). Site is the base sample unit and the estimated biomass of fishes per site is calculated by taking the mean values from the paired SPC surveys.

Similarly the mean percentage cover estimates per benthic functional group and complexity measures are calculated as site level means.

## Fish groupings

In this report, species data are summarized at three different levels: consumer group, size class, and total fish biomass (“all fishes”). Consumer groups are: “primary consumers” (herbivores and detritivores); “secondary consumers” (omnivores and benthic invertivores); “planktivores”; and “piscivores,” with classifications based on diet information taken largely from FishBase (Froese and Pauly, 2010; [Appendix 6: Species list](#)). The size classes used are 0–20, 20–50 and >50 cm TL.

## Generating island-scale estimates from the stratified design

Summary statistics (e.g., mean and variances) of survey quantities, e.g., biomass, are calculated by first averaging values within each stratum before calculating the reporting unit values. A weighted average method to calculate summary statistics is used because survey strata vary in size within each reporting unit.

Estimates of the mean and variance for each survey quantity considered are calculated based on the observed values at sampled sites within each stratum. Then aggregate estimates of the quantities across all strata are calculated using the formulas below. For example, with respect to biomass we have:

(1) pooled mean biomass ( $X$ ) across S strata:  $X = \sum_1^S (X_i * w_i)$  and;

(2) pooled variance of mean biomass ( $VAR$ ) across S strata:  $VAR = \sum_1^S (VAR_i * w_i^2)$

where  $X_i$  is the estimate of mean biomass within stratum  $i$ ,  $VAR_i$  is the estimated variance of  $X_i$  and  $w_i$  is the stratum-weighting factor. Strata weighting factors were based on the size of strata, i.e., if a stratum is 50% of the total area in an island then its weighting factor will be 0.5, and total of all weighting factors in an island sums to 1 (Smith et al. 2011).

In this report, only data from sites surveyed under the stratified sampling design are used, i.e., data collected from 2009 onwards; [Appendix 7: Random stratified sites surveyed at each island per year](#). In the few cases where less than 2 sites were surveyed in a stratum in a reporting period, these sites were removed from the island-scale parameter estimates for that period.

To assess Pacific-wide patterns in reef fish assemblages, statistics of total fish biomass (i.e., all fishes) and biomass within each consumer group and size class (mean and variance) are calculated per island per year and then averaged across years. In the section on U.S. Pacific reefs, summary graphs and metrics were generated from data collected since 2009 (see [Section: U.S. Pacific reefs status](#)).

Island-scale values for total fish biomass (i.e., all fishes) and biomass per consumer group and size class (mean and variance) are calculated by year (see [Section: Island status and trends](#)). Thus far, the time series under the stratified sampling design is too short to infer temporal trends<sup>1</sup>.

All data handling and analyses were performed using raw site data extracted from the NOAA CRED Oracle database, processed using a set of routine processing scripts written in R (R Development Core Team 2011) (Figure 4 post field), and visualized using the ggplot2 package. The site level data used to generate all figures and summary statistics are reported in [Appendix 8: Site level data](#).

---

<sup>1</sup> Since the towed diver survey method has not changed since 2002, these data can be used to assess temporal trends in large fish (> 50 cm total length). These data are available upon request: nmfs.pic.credinfo@noaa.gov

## U.S. Pacific reefs status

This section summarizes variation in reef fish community biomass across the following U.S. Pacific island regions; American Samoa, the main and Northwestern Hawaiian Islands, the Mariana Archipelago and the Pacific Remote Island Areas. The islands and atolls in the regions surveyed span broad biogeographic, geologic, oceanographic and human-impact gradients. Thus, patterns in the biological community will be influenced by a combination of these factors. There will also be within island habitat variability that affects the reef fish assemblages surveyed. For instance, several islands have a variety of habitat types, including fore reef, lagoon, and back reef habitats and for the purpose of this pan-Pacific comparison, only fore reef data are presented.

At the region scale, the highest mean total fish biomass was recorded in the Pacific Remote Island Areas (mean  $\pm$  standard error:  $143 \pm 7.1 \text{ g m}^{-2}$ ), followed in decreasing order by the Northwestern Hawaiian Islands ( $126 \pm 7.1 \text{ g m}^{-2}$ ), the northern Mariana Archipelago ( $71 \pm 4.7 \text{ g m}^{-2}$ ), American Samoa ( $46 \pm 2.1 \text{ g m}^{-2}$ ), the main Hawaiian Islands ( $26 \pm 1 \text{ g m}^{-2}$ ), and the southern Mariana Archipelago ( $19 \pm 0.8 \text{ g m}^{-2}$ ) (Figure 5 All fishes). Fish biomass is summarized by consumer group and size class in Figures 5 and 6 and Table 2). The regional mean (+/- standard error) values for total fish biomass and biomass per size class that are reported in this section are plotted as reference points for visual comparison in the following [Island status and trends](#) section.

## Consumer groups

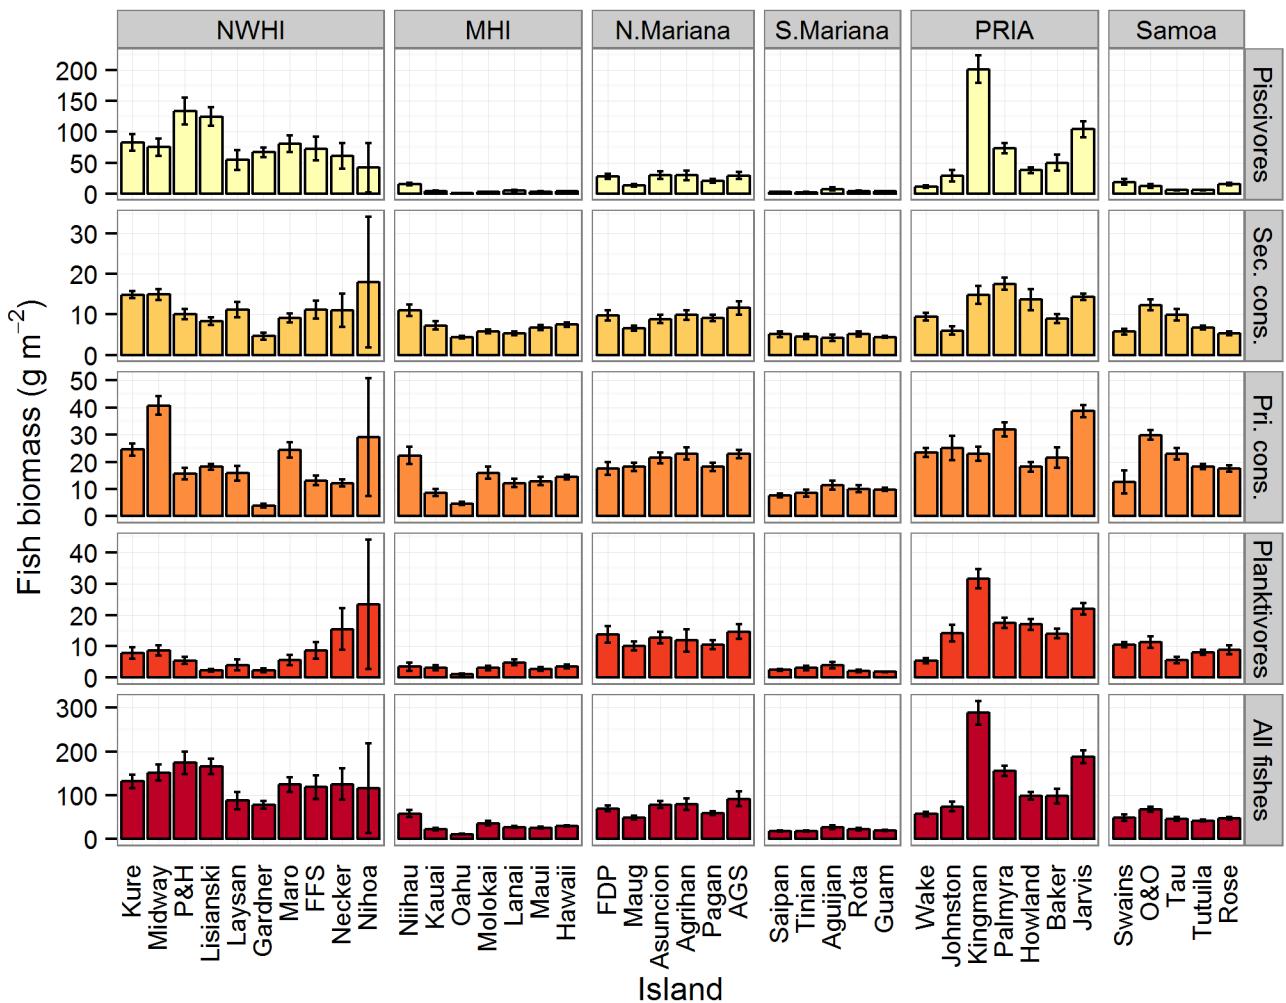

Figure 5 Mean fish biomass ( $\text{g m}^{-2}$ ) by consumer group per U.S. Pacific reef area. Mean fish biomass ( $\pm$  standard error) per consumer group per reef area pooled across survey years (2009–2014). Islands are ordered within region by latitude. See Appendix 6 for the species per consumer group classification scheme. See Appendix 4 and Appendix 7 for the sampling density per strata at each island by year and Appendix 8 for the site level data used to produce the graph. NWHI = Northwestern Hawaiian Islands, MHI = main Hawaiian Islands, N. Mariana = northern Mariana Archipelago, S. Mariana = southern Mariana Archipelago, PRIA = Pacific Remote Island Areas, Samoa = American Samoa, Sec. consumers = secondary consumers (invertebrates), Pri. Consumers = primary consumers (herbivores).

## Size classes

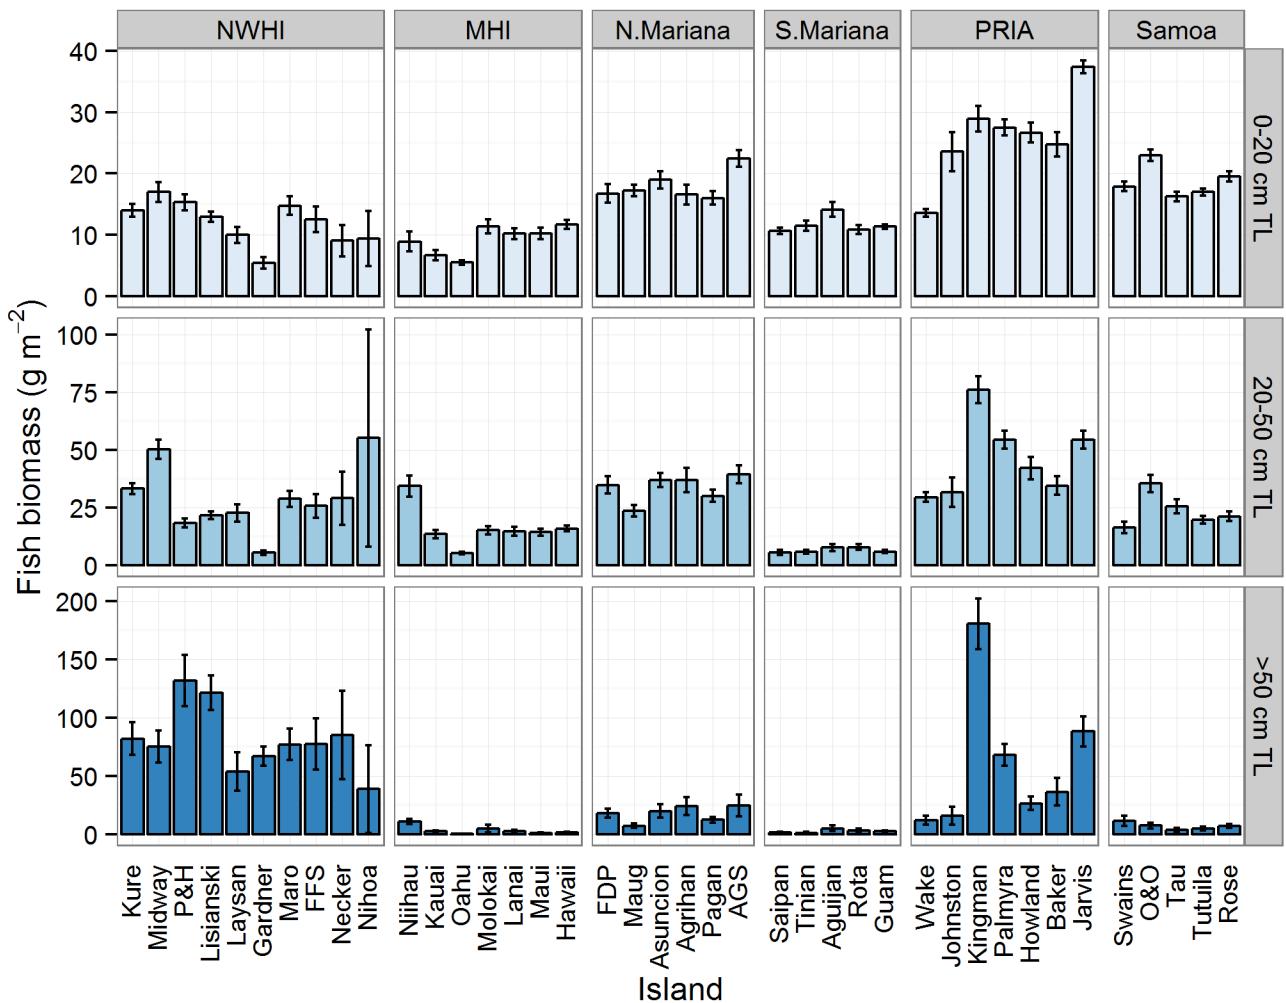

Figure 6 Mean fish biomass ( $\text{g m}^{-2}$ ) per size class per U.S. Pacific reef areas. Mean fish biomass ( $\pm$  standard error) per size class (0–20 cm, 20–50 and > 50 cm in total length (TL)) per reef area pooled across survey years (2009–2014). Islands are ordered within region by latitude. See [Appendix 4](#) and [Appendix 7](#) for the sampling density per strata at each island by year and [Appendix 8](#) for the site level data. NWHI = Northwestern Hawaiian Islands, MHI = main Hawaiian Islands, N. Mariana = northern Mariana Archipelago, S. Mariana = southern Mariana Archipelago, PRIA = Pacific Remote Island Areas, Samoa = American Samoa, TL = total length.

Table 2 Mean fish biomass ( $\text{g m}^{-2}$ ) with standard error in parentheses for all fish biomass, biomass per consumer group and per size class for forereef habitat. NWHI = Northwestern Hawaiian Islands, MHI = main Hawaiian Islands, N.Mariana = northern Mariana Archipelago (Farallon de Pajaros down to Sarigan), S. Mariana = southern Mariana Archipelago (Saipan, Tinian, Aguijan, Rota, and Guam), PRIA = Pacific Remote Island Areas, Samoa = American Samoa, Sec.consumers = secondary consumers, Pri. Consumers = primary consumers, TL = total length.

Region	Sites <sup>1</sup>	All fishes	Piscivores	Sec. consumers	Pri. consumers	Planktivores	0–20 cm TL	20–50 cm TL	> 50 cm TL

<sup>1</sup> The number of forereef sites surveyed during 2009–2014.

## **Island status and trends**

This section summarizes data collected at each island in 2009–2014. For each island within region, maps illustrate the site level data from the past and most recent surveys and a standard set of graphs show summary information on the fish and benthic community at the island scale. On each fish biomass graph, a reference line indicates the regionwide mean estimate, provided as a relevant regional comparison for island-level estimates.

# Northern Mariana Islands

## Alamagan, Guguan, and Sarigan Islands (AGS)

Alamagan, Guguan, and Sarigan Islands were surveyed in 2009 ( $n = 19$ ), 2011 ( $n = 24$ ), and 2014 ( $n = 33$ ). These islands are treated as a single reporting unit, as per our survey design (See Methods Sampling domain and design section).

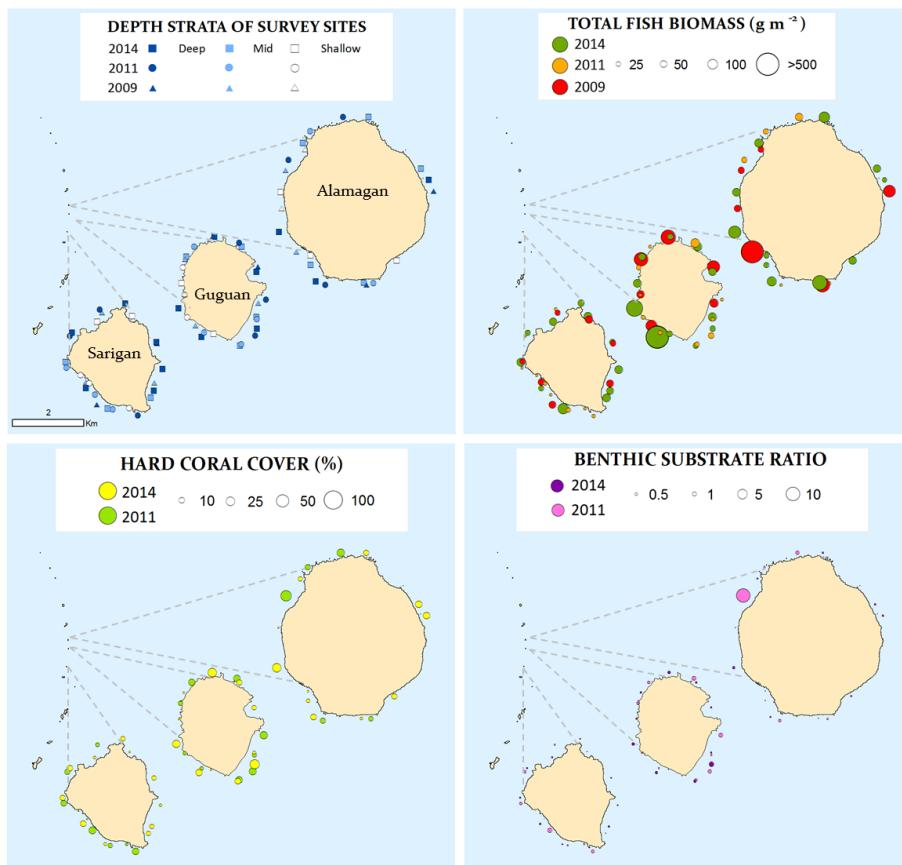

Figure 7 Alamagan, Guguan, and Sarigan Islands site survey data 2009, 2011 and 2014 identified by depth strata (top left). Total fish biomass recorded at each site per year (top right). Hard coral cover (%) assessed by rapid visual assessment (bottom left). Benthic substrate ratio (hard coral plus encrusting algae / turf and macroalgae) (bottom right). This ratio indicates the balance between the benthic components that contribute to reef accretion (coral and crustose coralline algae) compared to fleshy macroalgae and turf algae that compete for space on a reef.

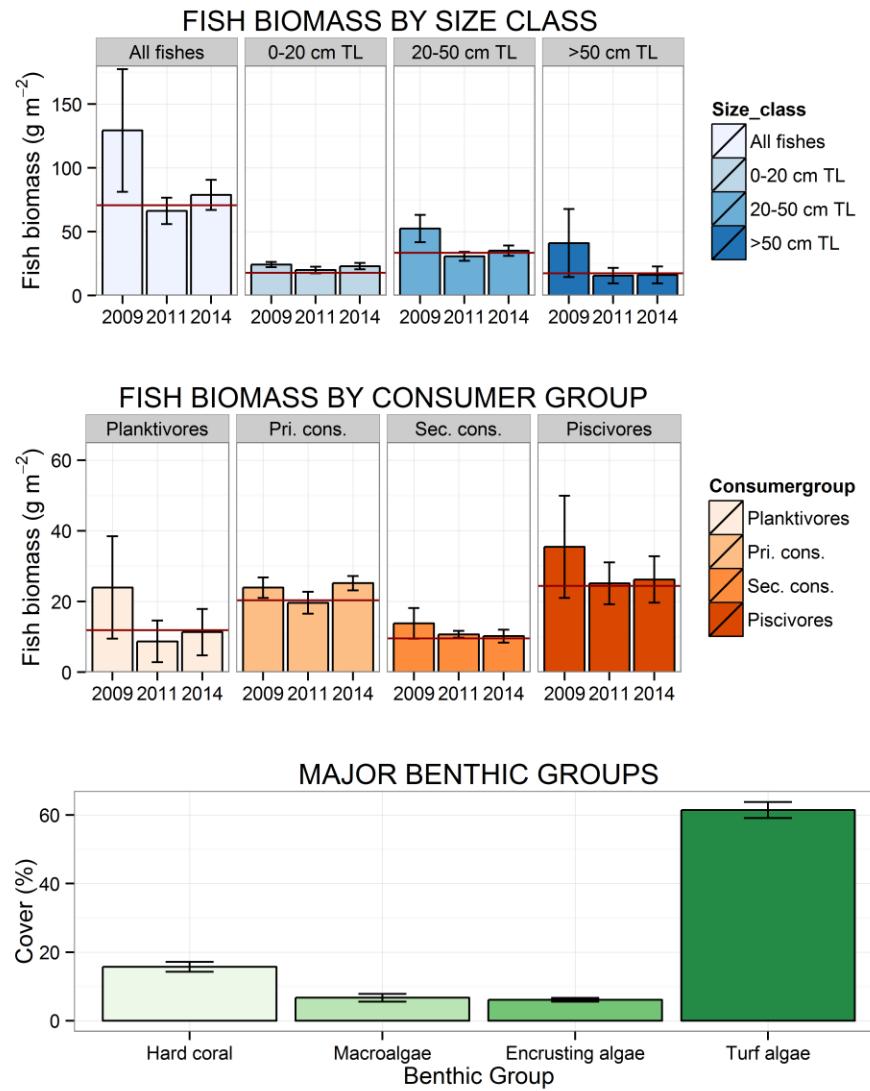

Figure 8 Alamagan, Guguan, and Sarigan Islands fish and benthic plots showing the biomass ( $\text{g m}^{-2} \pm \text{SE}$ ) of fish observed in total and per size class (top) and per consumer group (middle) and the percentage cover ( $\pm \text{SE}$ ) of the benthos. The benthic estimates are pooled across all years. The northern Mariana region mean estimates are plotted for reference (red line).

## Asuncion Island

Asuncion Island was surveyed in 2009 (n=13), 2011 (n=20), and 2014 (n=21).

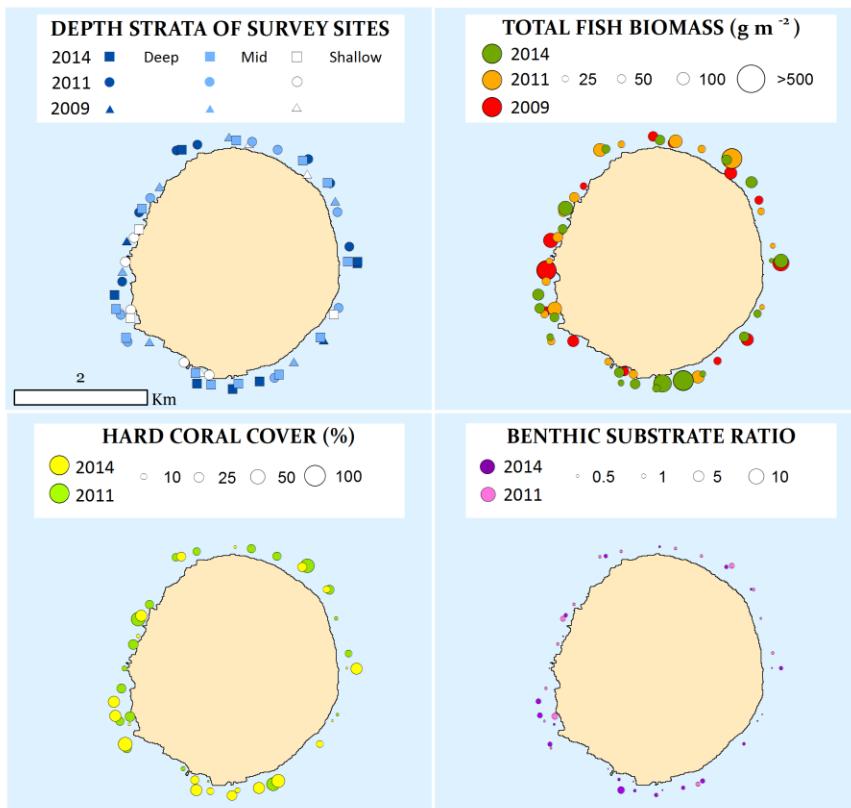

Figure 9 Asuncion Island site survey data 2009, 2011, and 2014 identified by depth strata (top left). Total fish biomass recorded at each site per year (top right). Hard coral cover (%) assessed by rapid visual assessment (bottom left). Benthic substrate ratio (hard coral plus encrusting algae / turf and macroalgae) (bottom right). This ratio indicates the balance between the benthic components that contribute to reef accretion (coral and crustose coralline algae) compared to fleshy macroalgae and turf algae that compete for space on the reef.

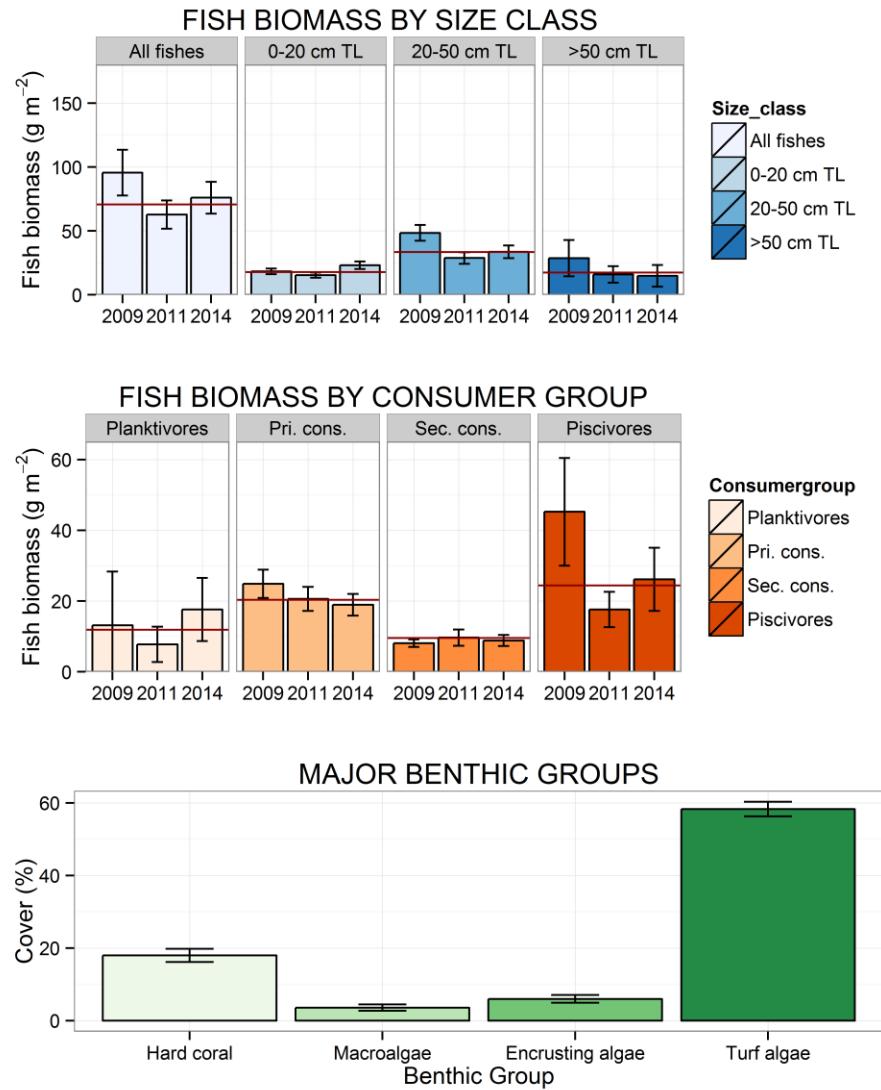

Figure 10 Asuncion Island fish and benthic plots showing the biomass ( $\text{g m}^{-2} \pm \text{SE}$ ) of fish observed in total and per size class (top) and per consumer group (middle) and the percentage cover ( $\pm \text{SE}$ ) of the benthos. The benthic estimates are pooled across all years. The northern Mariana region mean estimates are plotted for reference (red line).

## Farallon de Pajaros Island

Farallon de Pajaros Island was surveyed in 2009 ( $n=7$ ), 2011 ( $n=12$ ), and 2014 ( $n=11$ ).

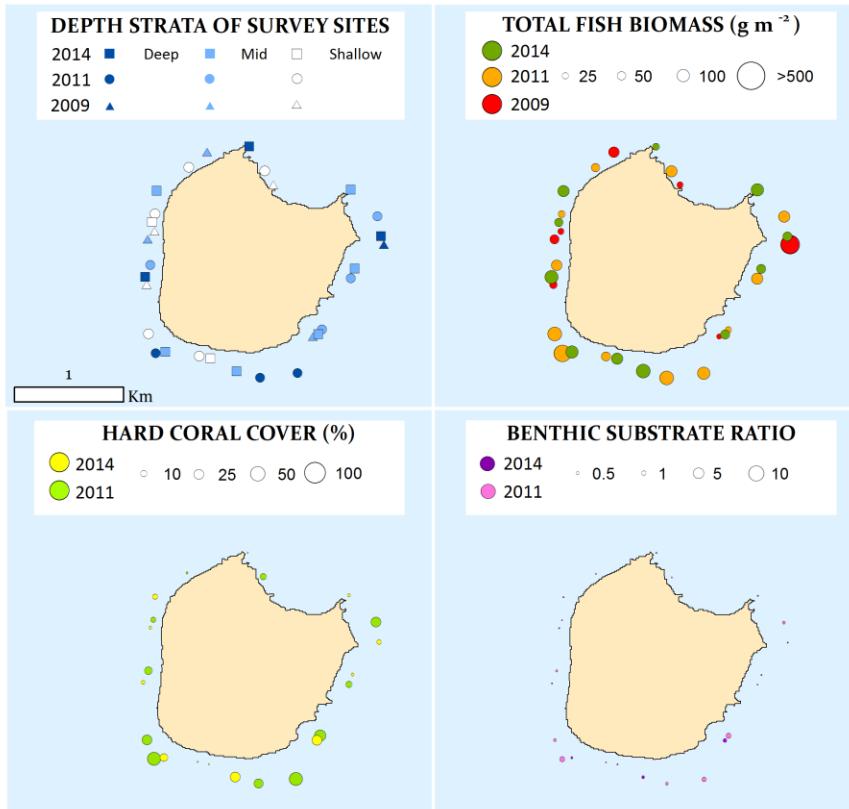

Figure 11 Farallon de Pajaros Island site survey data 2009, 2011, and 2014 identified by depth strata (top left). Total fish biomass recorded at each site per year (top right). Hard coral cover (%) assessed by rapid visual assessment (bottom left). Benthic substrate ratio (hard coral plus encrusting algae / turf and macroalgae) (bottom right). This ratio indicates the balance between the benthic components that contribute to reef accretion (coral and crustose coralline algae) compared to fleshy macroalgae and turf algae that compete for space on the reef.

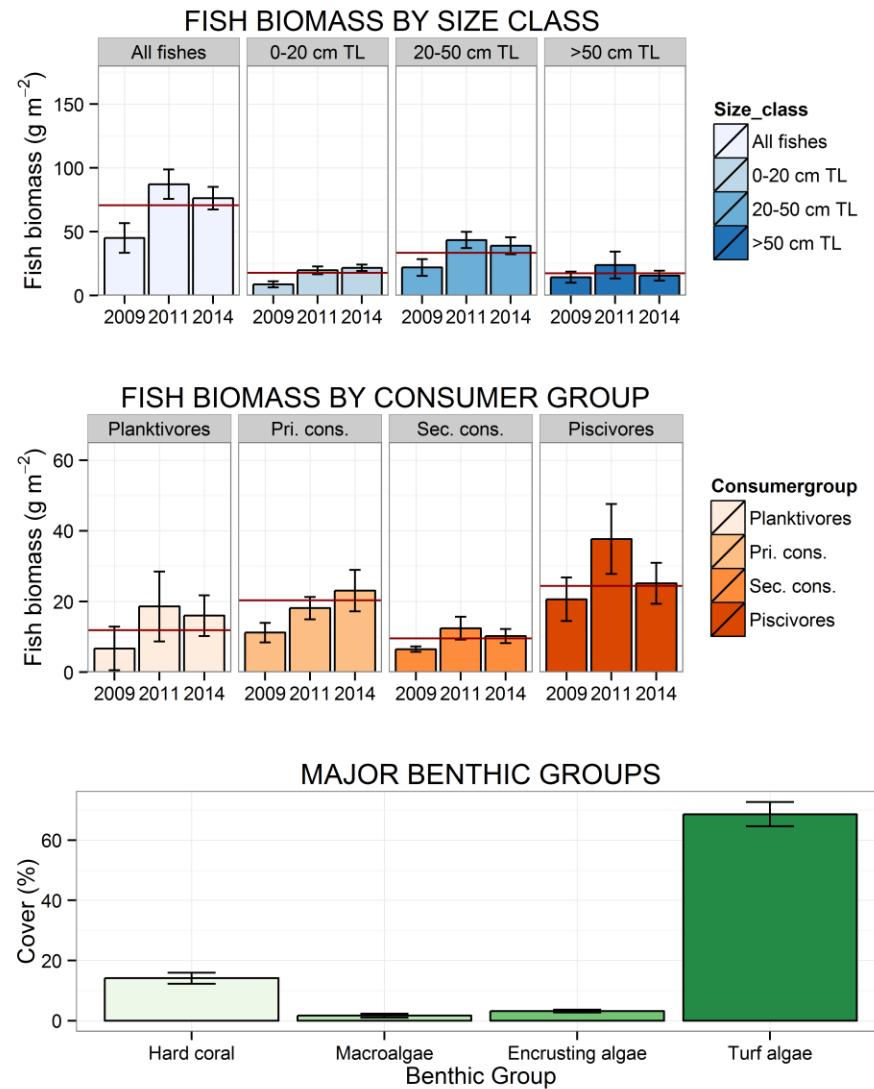

Figure 12 Farallon de Pajaros Island fish and benthic plots showing the biomass ( $\text{g m}^{-2} \pm \text{SE}$ ) of fish observed in total and per size class (top) and per consumer group (middle) and the percentage cover ( $\pm \text{SE}$ ) of the benthos. The benthic estimates are pooled across all years. The northern Mariana region mean estimates are plotted for reference (red line).

## Maug Island

Maug Island was surveyed in 2009 (n=21), 2011 (n=30), and 2014 (n=40).

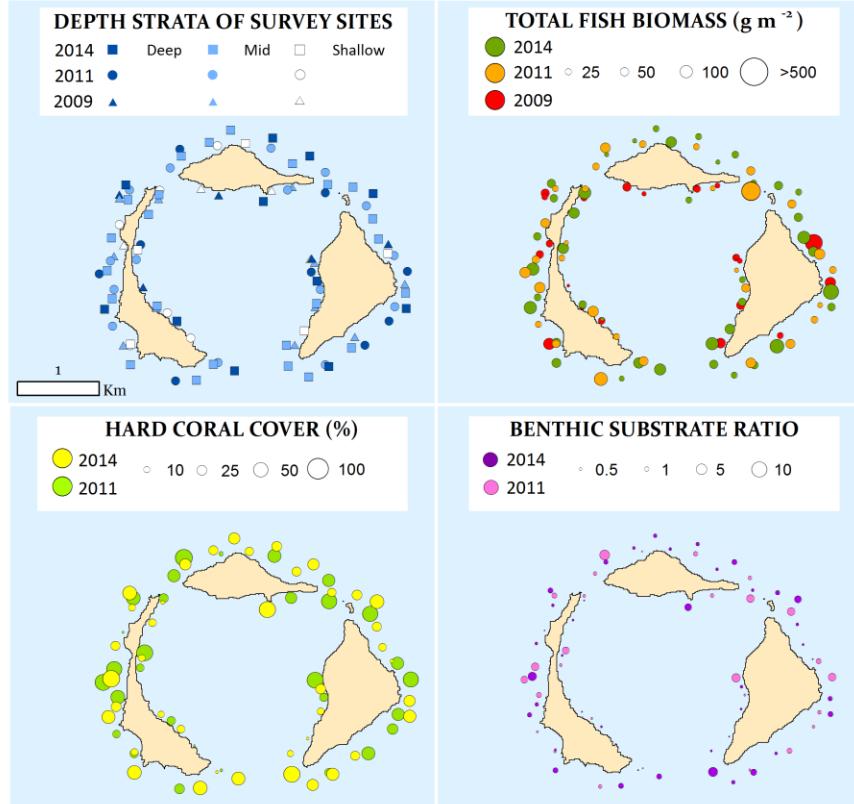

Figure 13 Maug Island site survey data 2009, 2011, and 2014 identified by depth strata (top left). Total fish biomass recorded at each site per year (top right). Hard coral cover (%) assessed by rapid visual assessment (bottom left). Benthic substrate ratio (hard coral plus encrusting algae / turf and macroalgae) (bottom right). This ratio indicates the balance between the benthic components that contribute to reef accretion (coral and crustose coralline algae) compared to fleshy macroalgae and turf algae that compete for space on the reef.

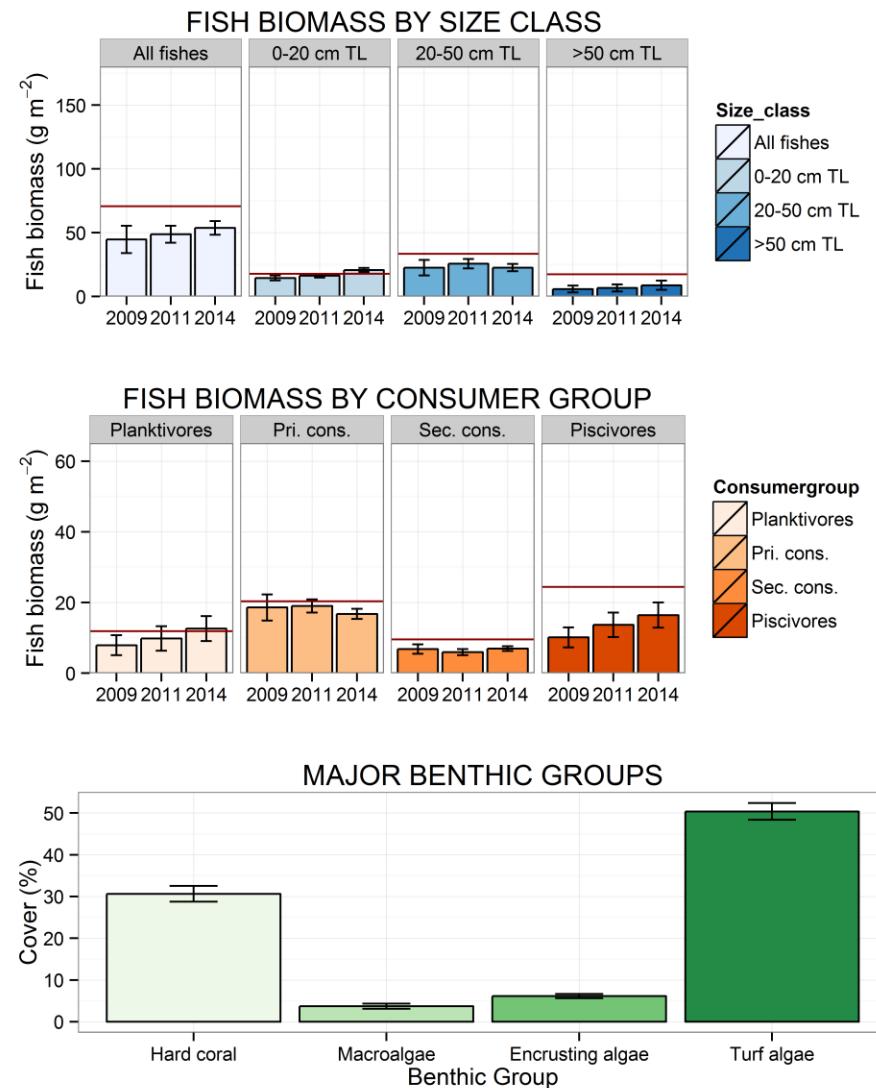

Figure 14 Maug Island fish and benthic plots showing the biomass ( $\text{g m}^{-2} \pm \text{SE}$ ) of fish observed in total and per size class (top) and per consumer group (middle) and the percentage cover ( $\pm \text{SE}$ ) of the benthos. The benthic estimates are pooled across all years. The northern Mariana region mean estimates are plotted for reference (red line).

## Pagan Island

Pagan Island was surveyed in 2009 (n=21), 2011 (n=29), and 2014 (n=43).

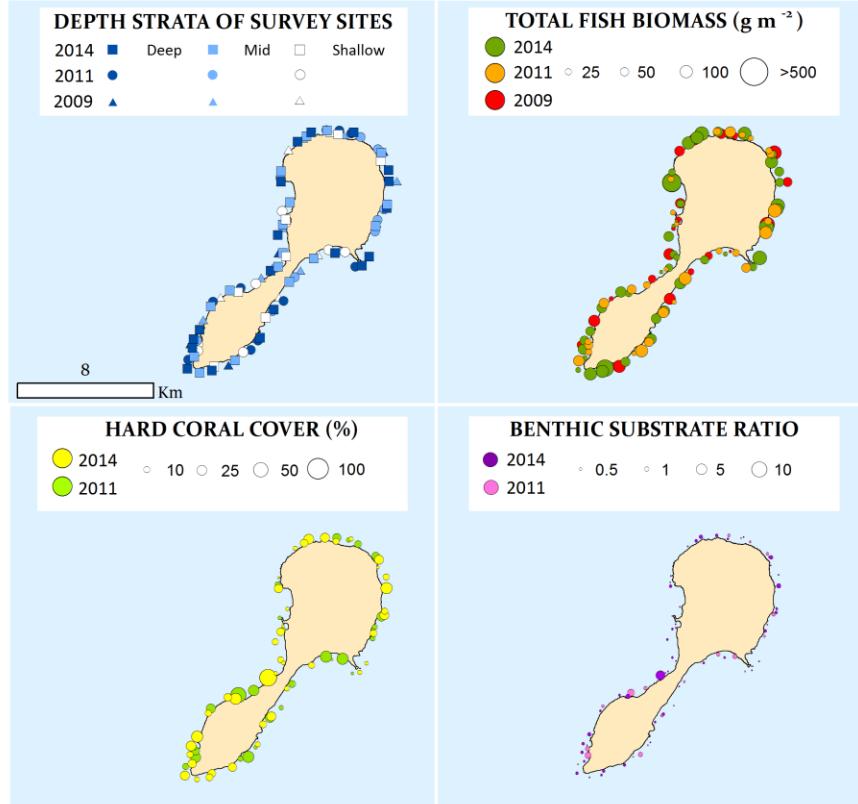

Figure 15 Pagan Island site survey data 2009, 2011, and 2014 identified by depth strata (top left). Total fish biomass recorded at each site per year (top right). Hard coral cover (%) assessed by rapid visual assessment (bottom left). Benthic substrate ratio (hard coral plus encrusting algae / turf and macroalgae) (bottom right). This ratio indicates the balance between the benthic components that contribute to reef accretion (coral and crustose coralline algae) compared to fleshy macroalgae and turf algae that compete for space on the reef.

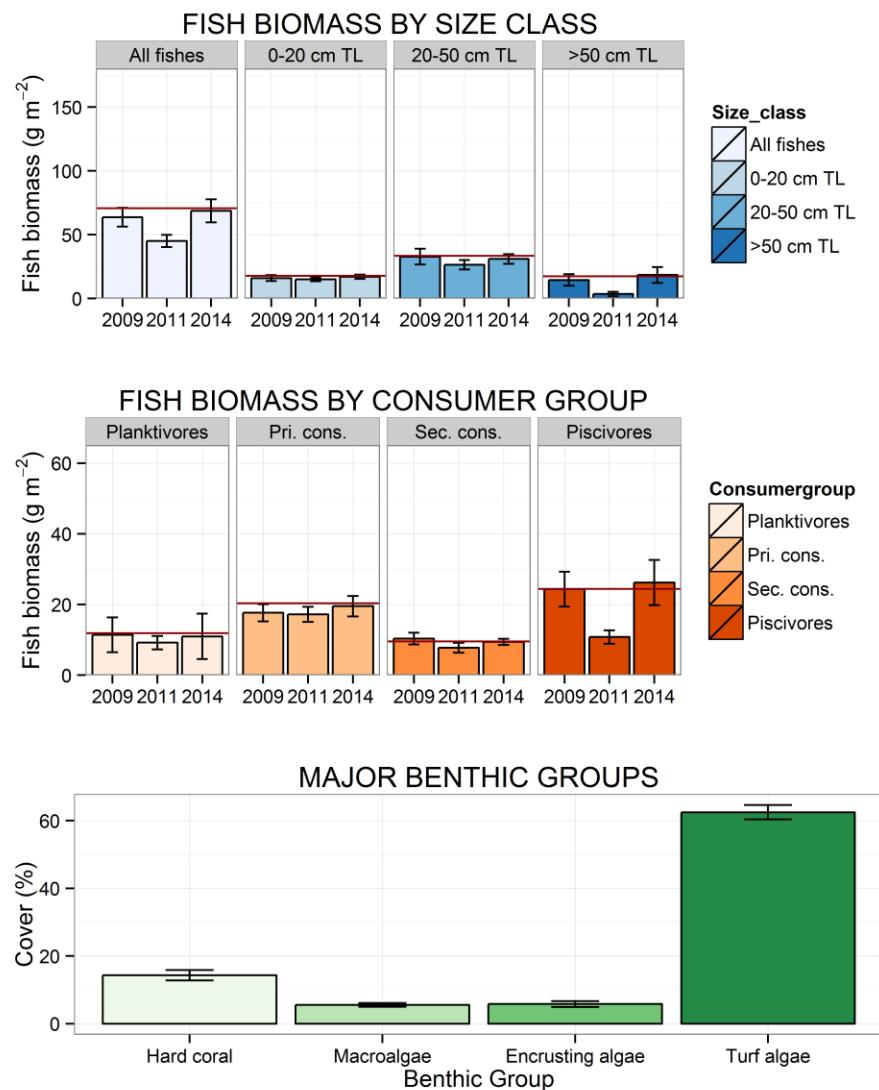

Figure 16 Pagan Island fish and benthic plots showing the biomass ( $\text{g m}^{-2} \pm \text{SE}$ ) of fish observed in total and per size class (top) and per consumer group (middle) and the percentage cover ( $\pm \text{SE}$ ) of the benthos. The benthic estimates are pooled across all years. The northern Mariana region mean estimates are plotted for reference (red line).

# Southern Mariana Islands

## Aguijan Island

Aguijan Island was surveyed in 2009 (n=6), 2011 (n=13), and 2014 (n=10).

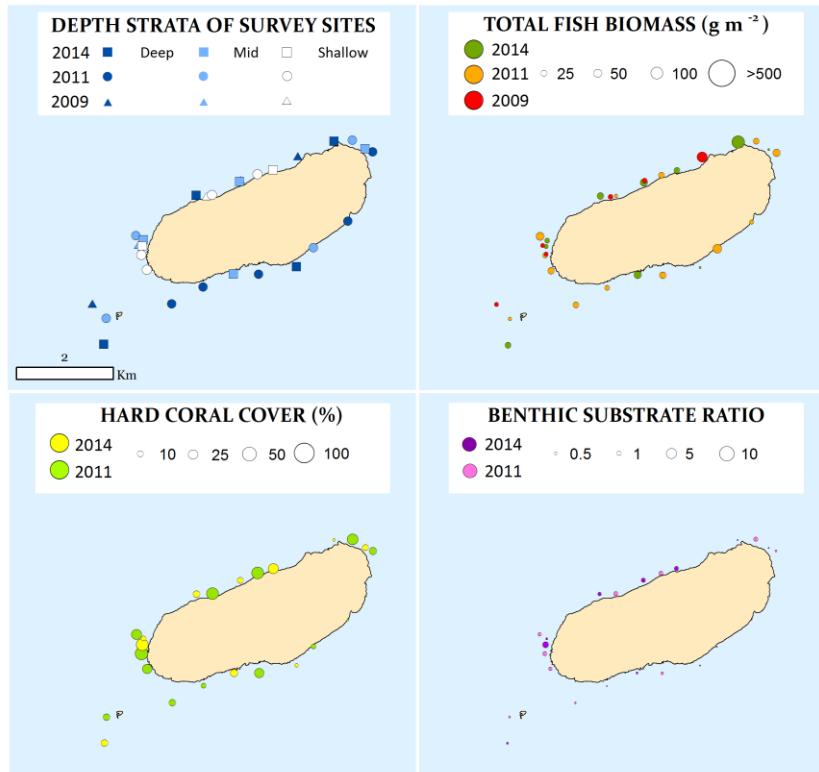

Figure 17 Aguijan Island site survey data 2009, 2011, and 2014 identified by depth strata (top left). Total fish biomass recorded at each site per year (top right). Hard coral cover (%) assessed by rapid visual assessment (bottom left). Benthic substrate ratio (hard coral plus encrusting algae / turf and macroalgae) (bottom right). This ratio indicates the balance between the benthic components that contribute to reef accretion (coral and crustose coralline algae) compared to fleshy macroalgae and turf algae that compete for space on the reef.

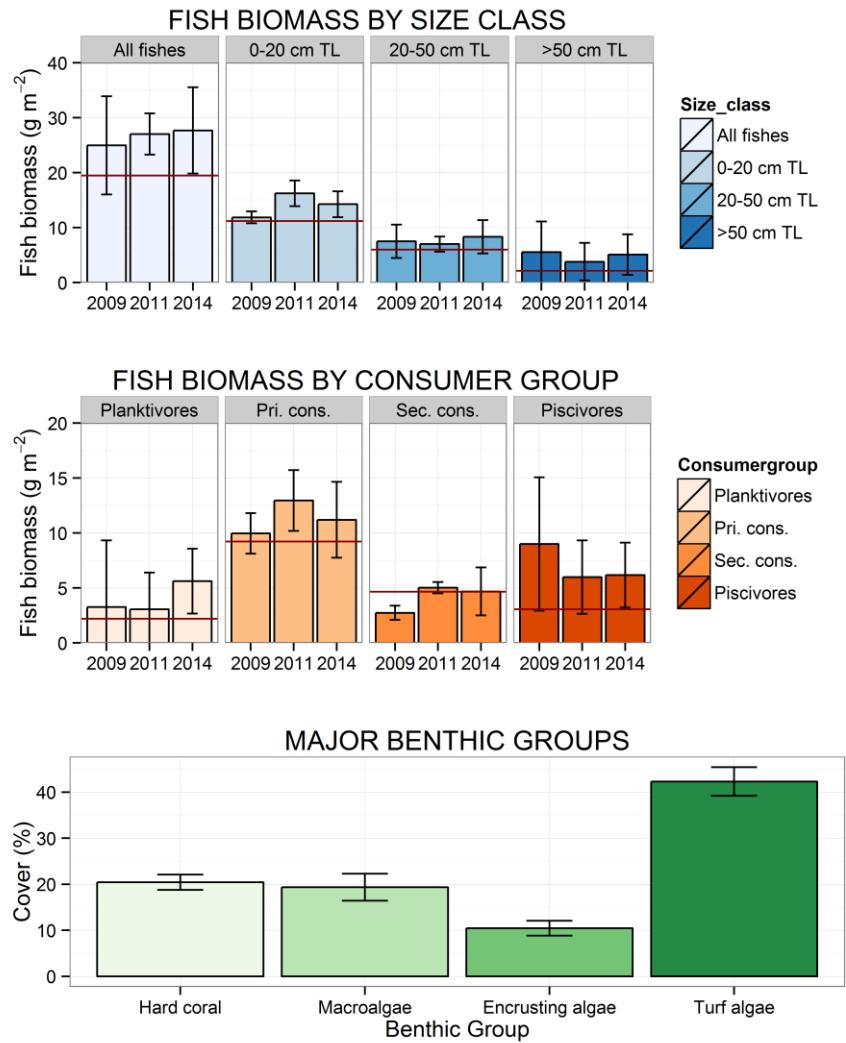

Figure 18 Aguijan Island fish and benthic plots showing the biomass ( $\text{g m}^{-2} \pm \text{SE}$ ) of fish observed in total and per size class (top) and per consumer group (middle) and the percentage cover ( $\pm \text{SE}$ ) of the benthos. The benthic estimates are pooled across all years. The southern Mariana region mean estimates are plotted for reference (red line).

## Guam Island

Guam Island was surveyed in 2009 (n=25), 2011 (n=133), and 2014 (n=93). In 2011, additional shore-based surveys contributed 89 sites, and in 2014, 20 additional shore-based surveys contributed to the total.

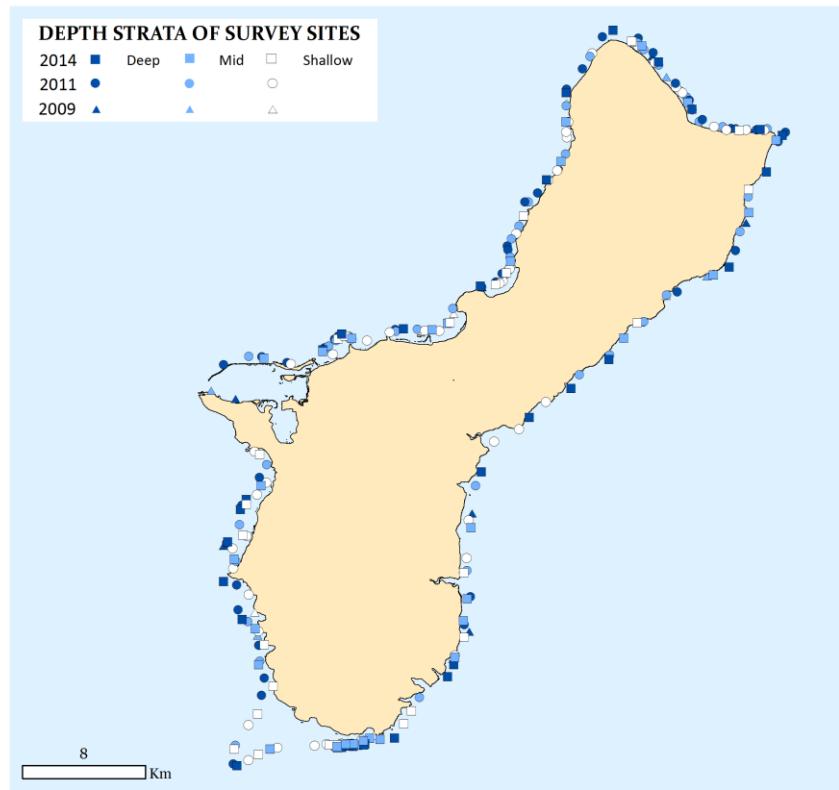

Figure 19 Guam Island site survey data 2009, 2011, and 2014 identified by depth strata.

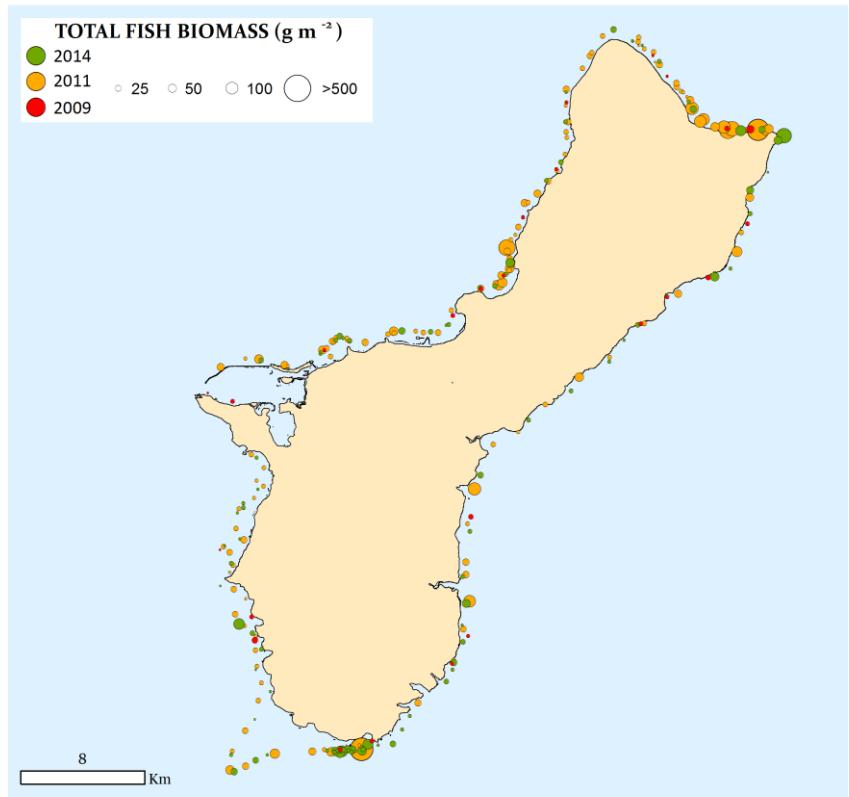

Figure 20 Total fish biomass recorded at each site per year.

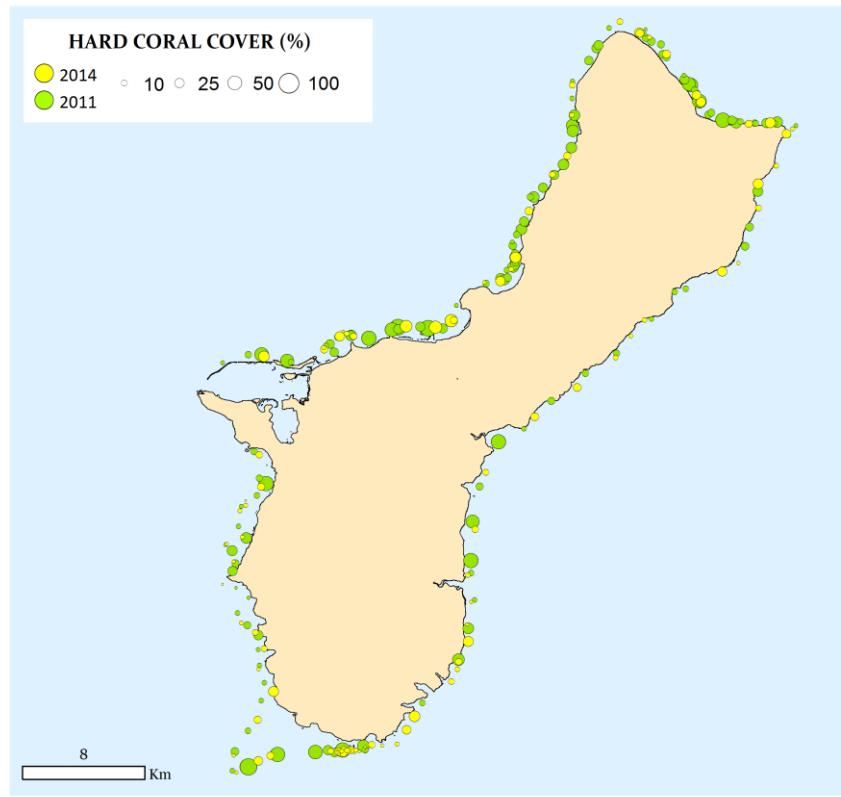

Figure 21 Hard coral cover (%) assessed by rapid visual assessment.

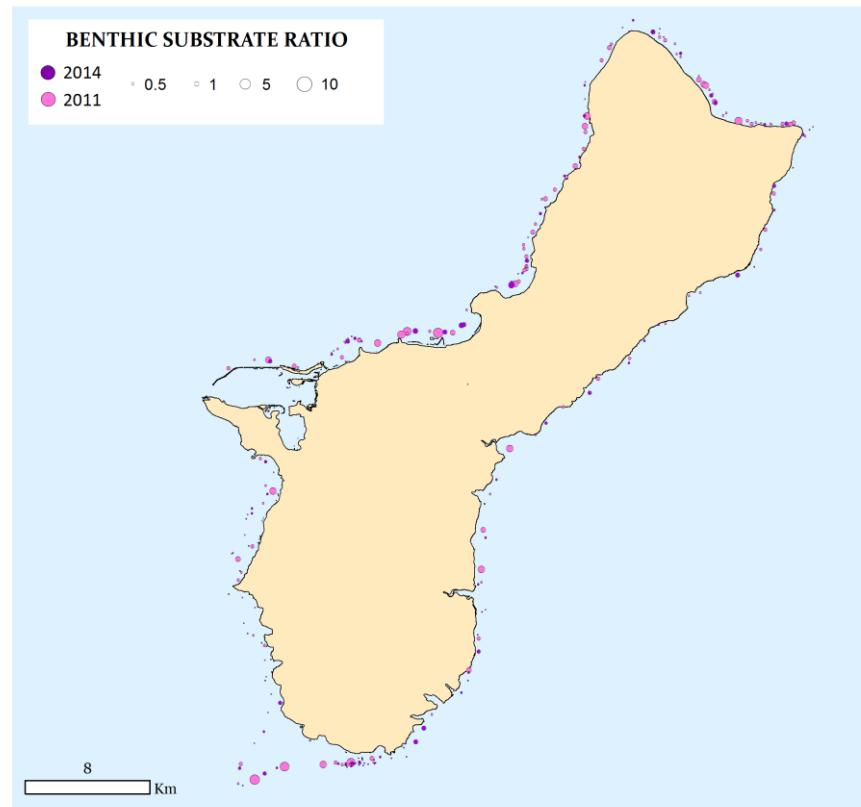

Figure 22 Benthic substrate ratio (hard coral plus encrusting algae / turf and macroalgae). This ratio indicates the balance between the benthic components that contribute to reef accretion (coral and crustose coralline algae) compared to fleshy macroalgae and turf algae that compete for space on the reef.

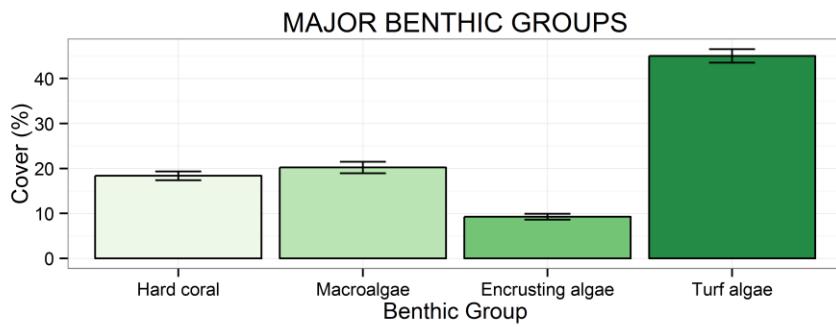

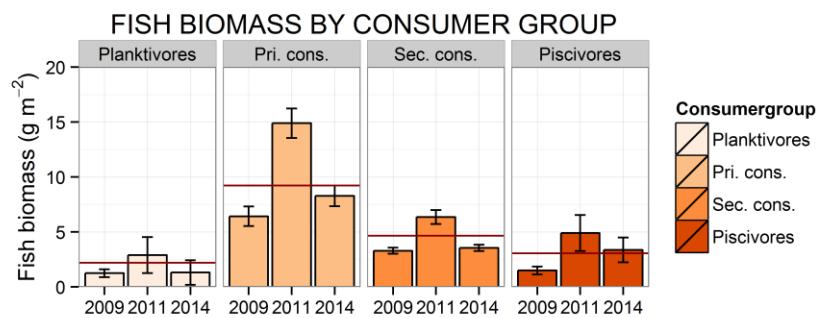

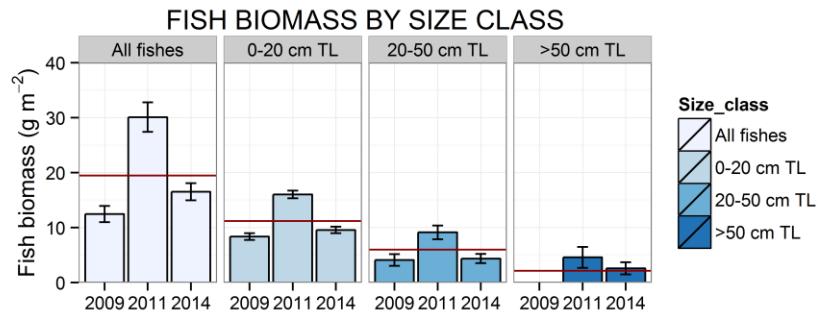

Figure 23 Guam Island fish and benthic plots showing the biomass ( $\text{g m}^{-2} \pm \text{SE}$ ) of fish observed in total and per size class (top) and per consumer group (middle) and the percentage cover ( $\pm \text{SE}$ ) of the benthos. The benthic estimates are pooled across all years. The southern Mariana region mean estimates are plotted for reference (red line).

## Rota Island

Rota was surveyed in 2009 (n =14), 2011 (n =24) and 2014 (n=28).

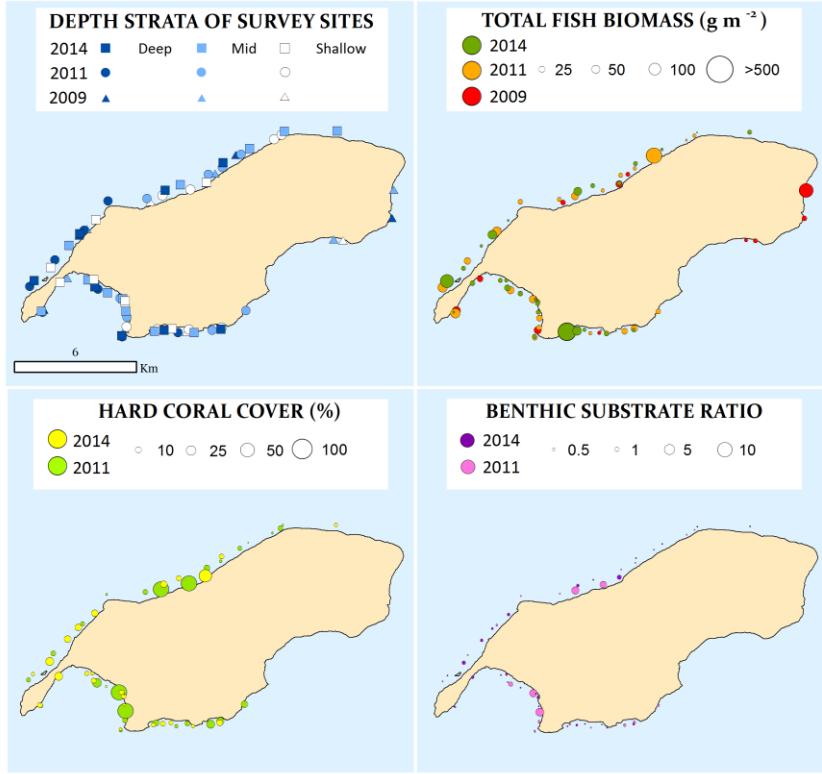

Figure 20 Rota Island site survey data 2009, 2011, and 2014 identified by depth strata (top left). Total fish biomass recorded at each site per year (top right). Hard coral cover (%) assessed by rapid visual assessment (bottom left). Benthic substrate ratio (hard coral plus encrusting algae / turf and macroalgae) (bottom right). This ratio indicates the balance between the benthic components that contribute to reef accretion (coral and crustose coralline algae) compared to fleshy macroalgae and turf algae that compete for space on the reef.

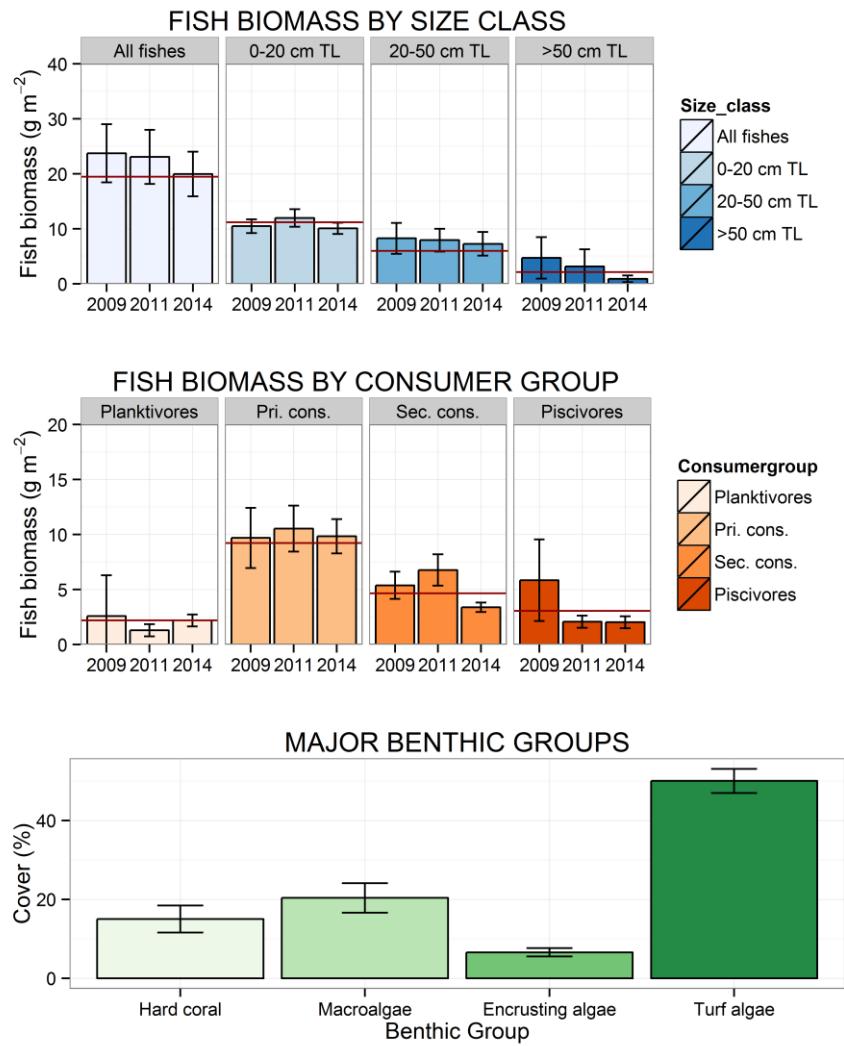

Figure 215 Rota Island fish and benthic plots showing the biomass ( $\text{g m}^{-2} \pm \text{SE}$ ) of fish observed in total and per size class (top) and per consumer group (middle) and the percentage cover ( $\pm \text{SE}$ ) of the benthos. The benthic estimates are pooled across all years. The southern Mariana region mean estimates are plotted for reference (red line).

## Saipan Island

Saipan Island was surveyed in 2009 (n =23), 2011 (n =30) and 2014 (n=48).

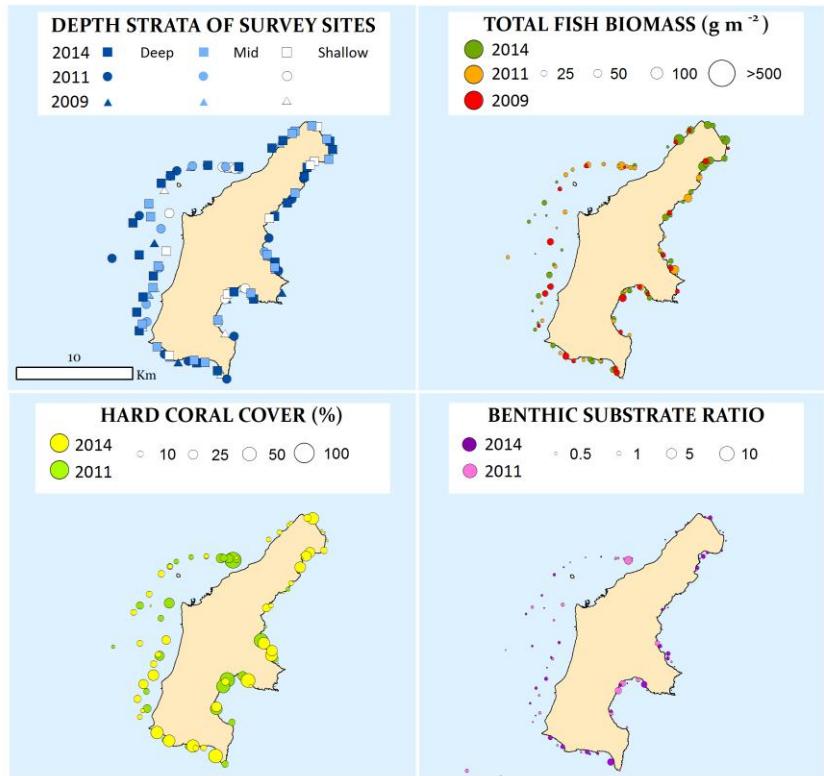

Figure 226 Saipan Island site survey data 2009, 2011, and 2014 identified by depth strata (top left). Total fish biomass recorded at each site per year (top right). Hard coral cover (%) assessed by rapid visual assessment (bottom left). Benthic substrate ratio (hard coral plus encrusting algae / turf and macroalgae) (bottom right). This ratio indicates the balance between the benthic components that contribute to reef accretion (coral and crustose coralline algae) compared to fleshy macroalgae and turf algae that compete for space on the reef.

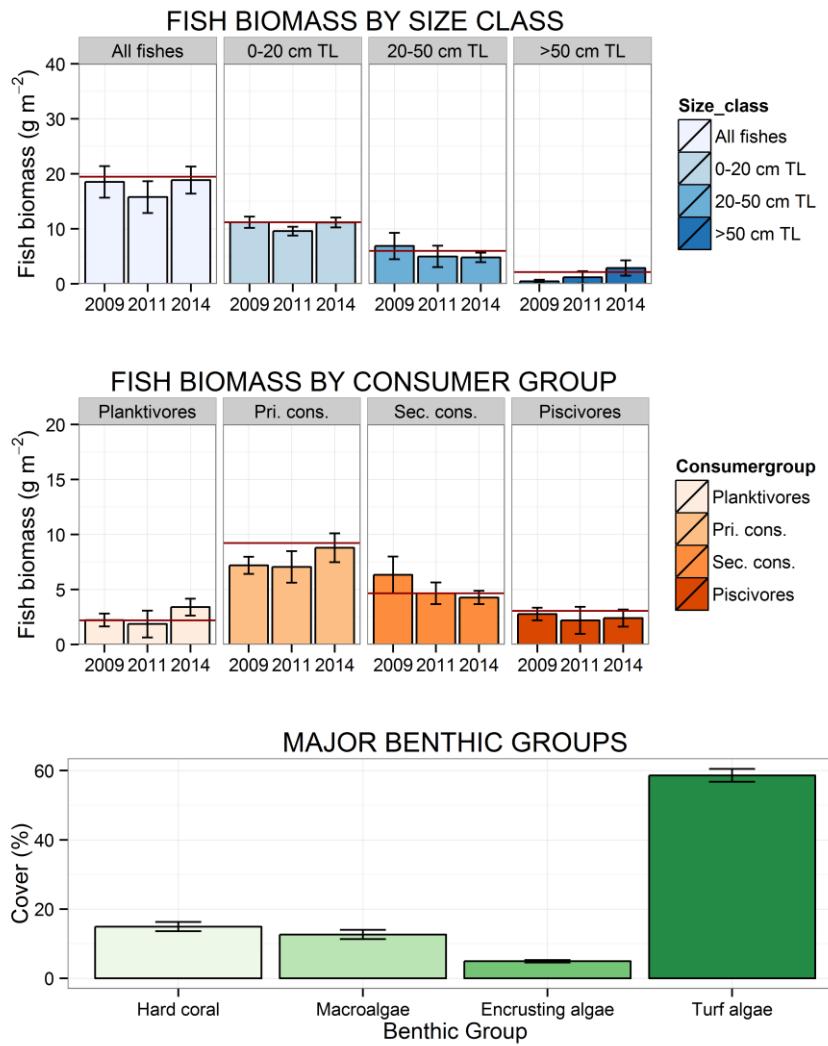

Figure 23 Saipan Island fish and benthic plots showing the biomass ( $\text{g m}^{-2} \pm \text{SE}$ ) of fish observed in total and per size class (top) and per consumer group (middle) and the percentage cover ( $\pm \text{SE}$ ) of the benthos. The benthic estimates are pooled across all years. The southern Mariana region mean estimates are plotted for reference (red line).

## Tinian Island

Tinian Island was surveyed in 2009 ( $n = 14$ ), 2011 ( $n = 19$ ) and 2014 ( $n = 19$ ).

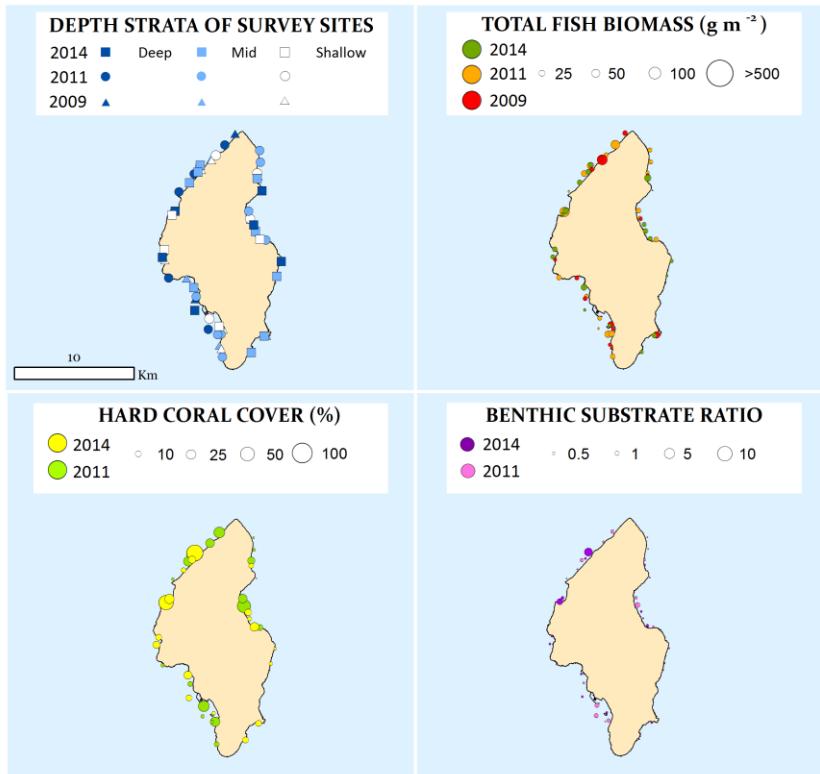

Figure 28 Tinian Island site survey data 2009, 2011, and 2014 identified by depth strata (top left). Total fish biomass recorded at each site per year (top right). Hard coral cover (%) assessed by rapid visual assessment (bottom left). Benthic substrate ratio (hard coral plus encrusting algae / turf and macroalgae) (bottom right). This ratio indicates the balance between the benthic components that contribute to reef accretion (coral and crustose coralline algae) compared to fleshy macroalgae and turf algae that compete for space on the reef.

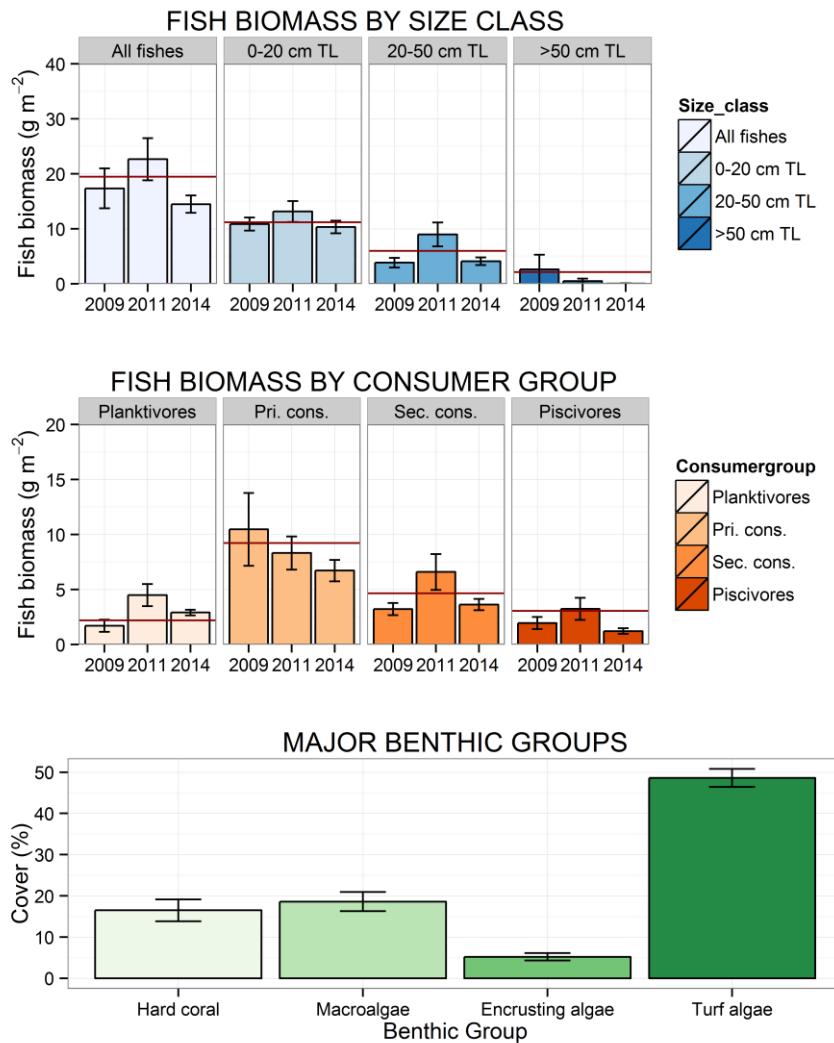

Figure 29 Tinian Island fish and benthic plots showing the biomass ( $\text{g m}^{-2} \pm \text{SE}$ ) of fish observed in total and per size class (top) and per consumer group (middle) and the percentage cover ( $\pm \text{SE}$ ) of the benthos. The benthic estimates are pooled across all years. The southern Mariana region mean estimates are plotted for reference (red line).

# Northwestern Hawaiian Islands

## French Frigate Shoals (FFS)

French Frigate Shoals were surveyed in 2010 (n = 27), 2011 (n=8), 2012 (n=15), and 2014 (n = 27). Results are shown for each habitat type surveyed: forereef, lagoon, and backreef in separate plots.

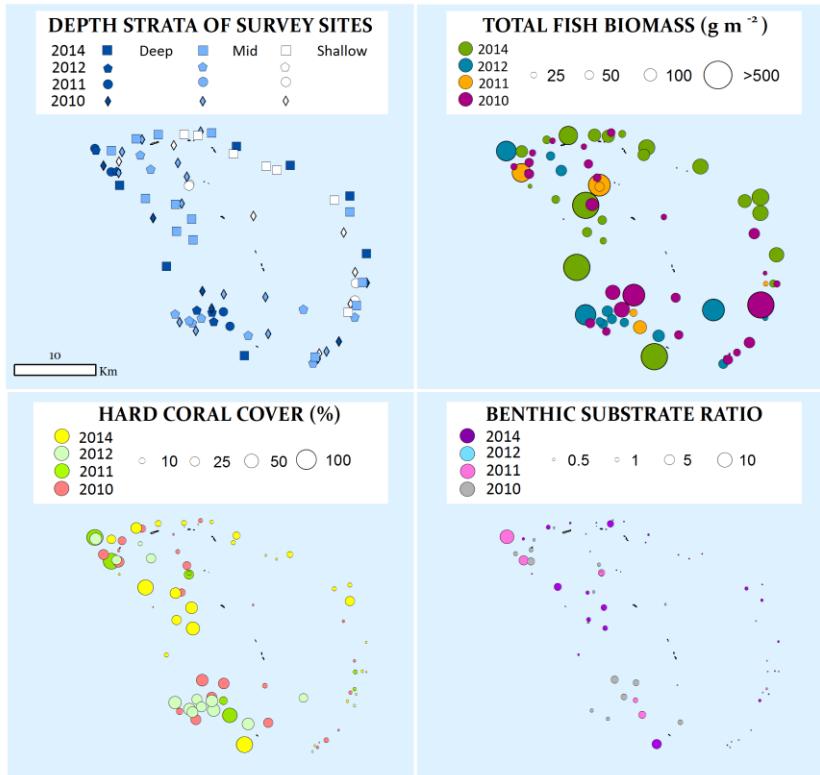

Figure 30 French Frigate Shoals site survey data 2010, 2011, 2012, and 2014 identified by depth strata (top left). Total fish biomass recorded at each site per year (top right). Hard coral cover (%) assessed by rapid visual assessment (bottom left). Benthic substrate ratio (hard coral plus encrusting algae / turf and macroalgae) (bottom right). This ratio indicates the balance between the benthic components that contribute to reef accretion (coral and crustose coralline algae) compared to fleshy macroalgae and turf algae that compete for space on the reef.

The forereef habitat was surveyed in 2010 (n =11), 2011 (n=2), 2012 (n=5), and 2014 (n =24).

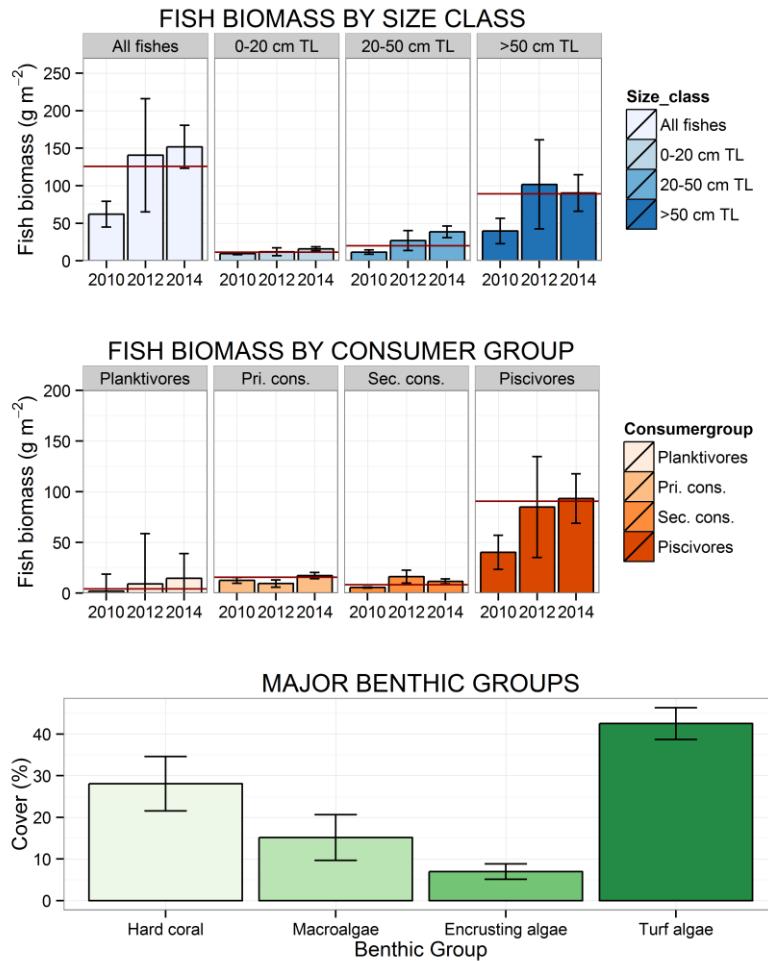

Figure 31 French Frigate Shoals fish and benthic plots showing the biomass ( $\text{g m}^{-2} \pm \text{SE}$ ) of fish observed in total and per size class (top) and per consumer group (middle) and the percentage cover ( $\pm \text{SE}$ ) of the benthos for forereef habitat only. Only 2 forereef sites were surveyed in 2011, so that data is not included. The benthic estimates are pooled across all years. The Northwestern Hawaiian Islands region mean forereef estimates are plotted for reference (red line).

The lagoon habitat was surveyed in 2010 (n = 16), 2011 (n = 6), and 2012 (n = 10).

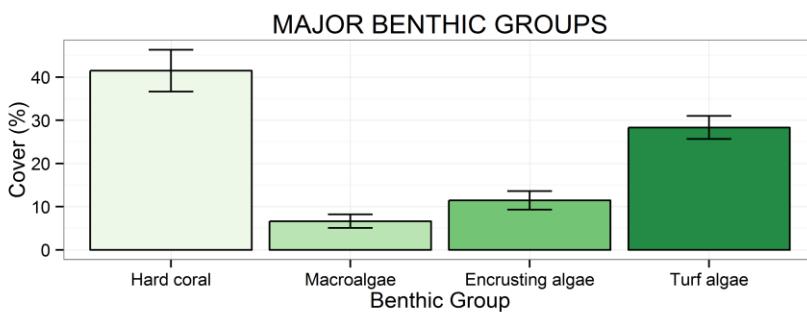

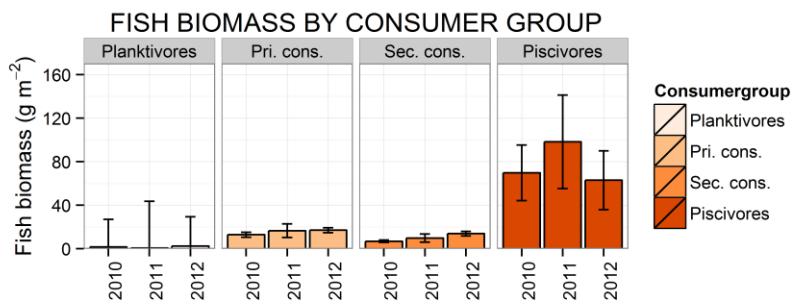

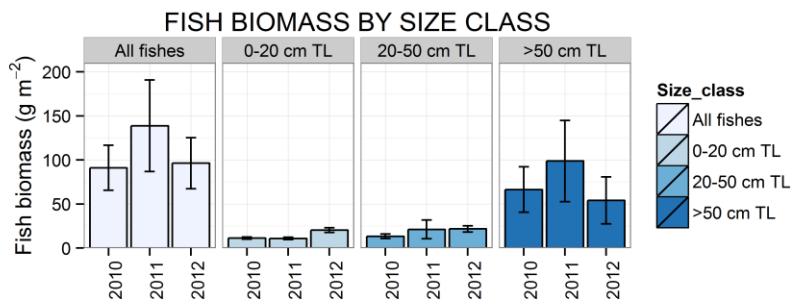

Figure 32 French Frigate Shoals fish and benthic plots showing the biomass ( $\text{g m}^{-2} \pm \text{SE}$ ) of fish observed in total and per size class (top) and per consumer group (middle) and the percentage cover ( $\pm \text{SE}$ ) of the benthos for lagoon habitat. The benthic estimates are pooled across all years. The Northwestern Hawaiian Islands region mean lagoon estimates are not plotted due to small sample size.

The backreef habitat was surveyed in 2014 (n = 3).

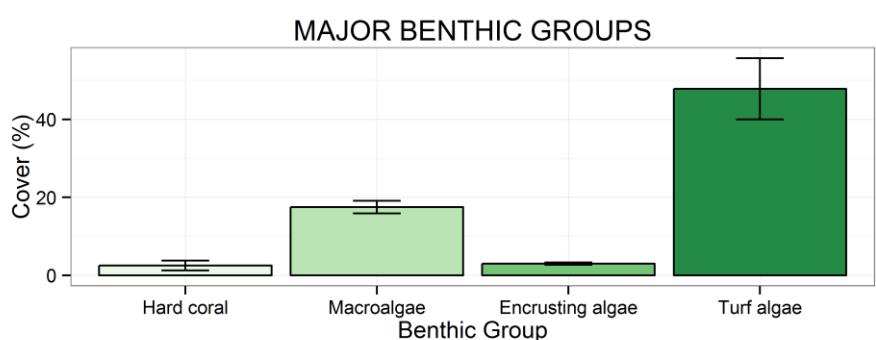

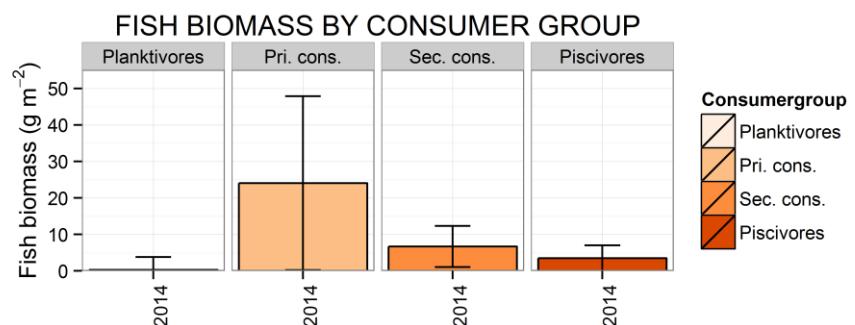

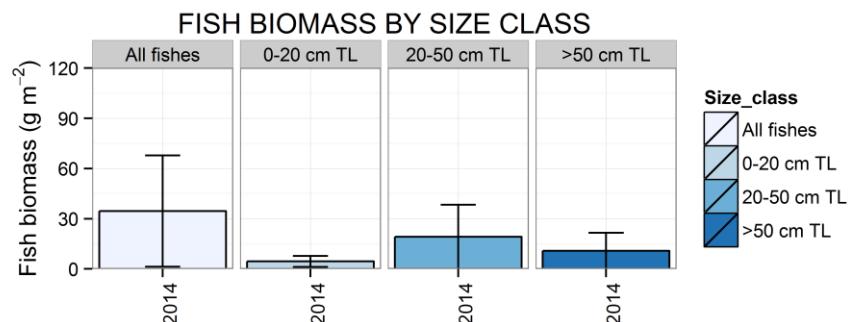

Figure 33 French Frigate Shoals fish and benthic plots showing the biomass ( $\text{g m}^{-2} \pm \text{SE}$ ) of fish observed in total and per size class (top) and per consumer group (middle) and the percentage cover ( $\pm \text{SE}$ ) of the benthos for backreef habitat. The Northwestern Hawaiian Islands region mean backreef estimates are not plotted due to small sample size.

## Lisianski Island

Lisianski Island was surveyed in 2009 (n=19), 2010 (n =25), 2011 (n=9), 2012 (n=25), and 2014 (n =28).

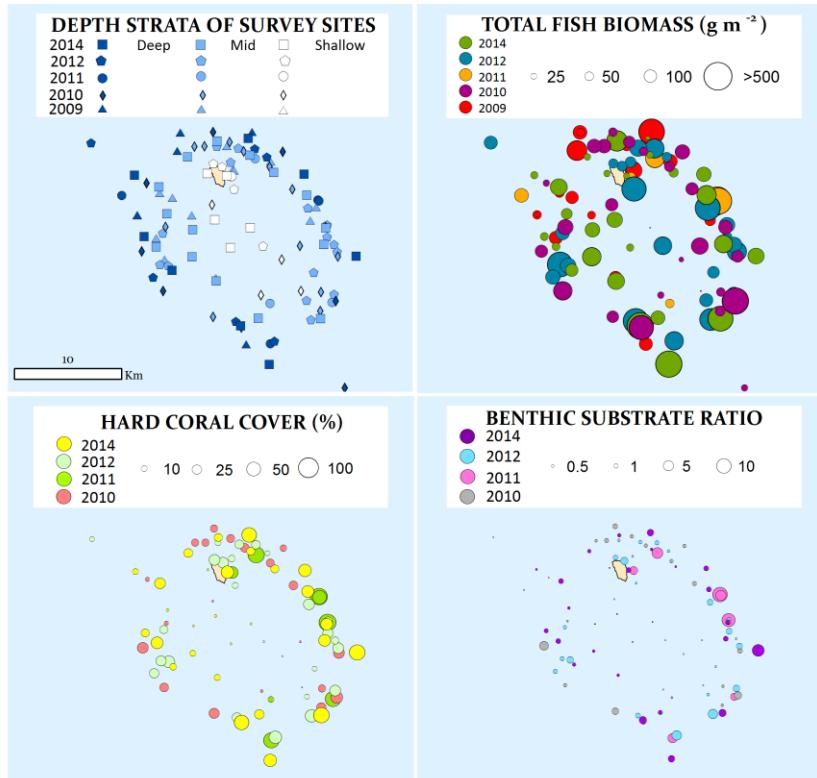

Figure 34 Lisianski Island site survey data 2009, 2010, 2011, 2012, and 2014 identified by depth strata (top left). Total fish biomass recorded at each site per year (top right). Hard coral cover (%) assessed by rapid visual assessment (bottom left). Benthic substrate ratio (hard coral plus encrusting algae / turf and macroalgae) (bottom right). This ratio indicates the balance between the benthic components that contribute to reef accretion (coral and crustose coralline algae) compared to fleshy macroalgae and turf algae that compete for space on the reef.

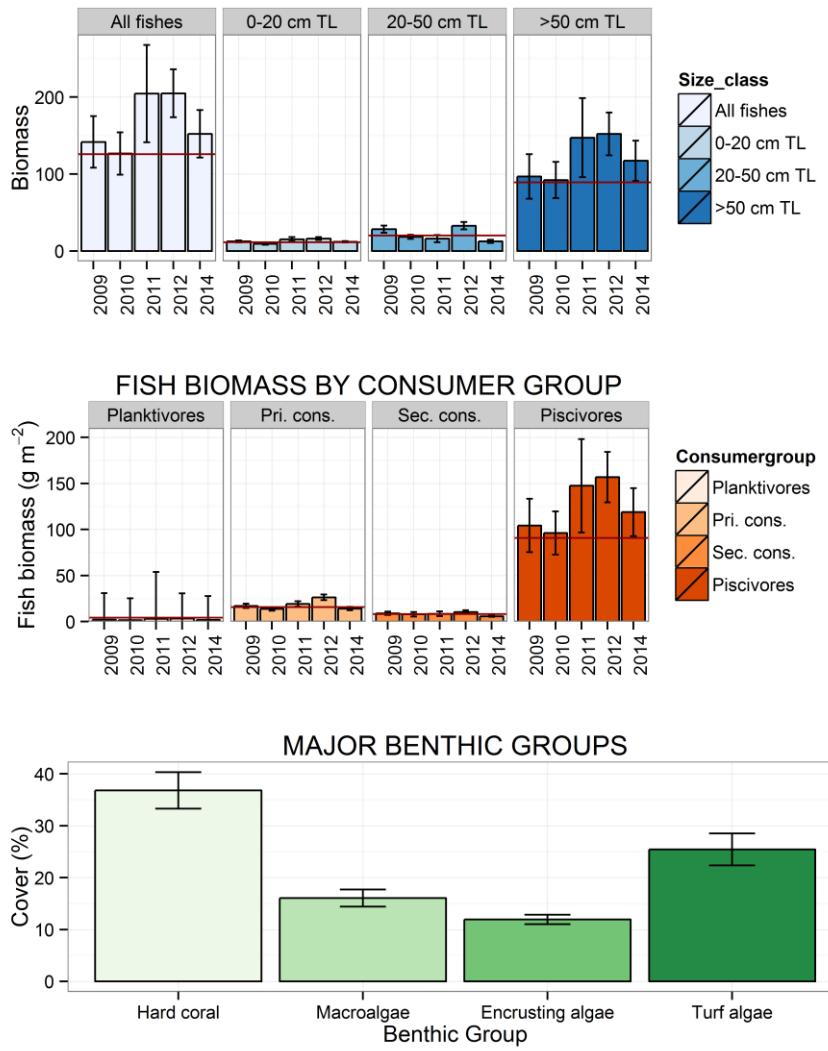

Figure 35 Lisianski Island fish and benthic plots showing the biomass ( $\text{g m}^{-2} \pm \text{SE}$ ) of fish observed in total and per size class (top) and per consumer group (middle) and the percentage cover ( $\pm \text{SE}$ ). The benthic estimates are pooled across all years. The Northwestern Hawaiian Islands region mean estimates are plotted for reference (red line).

## Midway Island

Midway Island was surveyed in 2009 (n =53), 2011 (n=30), and 2014 (n =34). Results are shown for each habitat type surveyed: fore reef, lagoon, and back reef in separate plots.

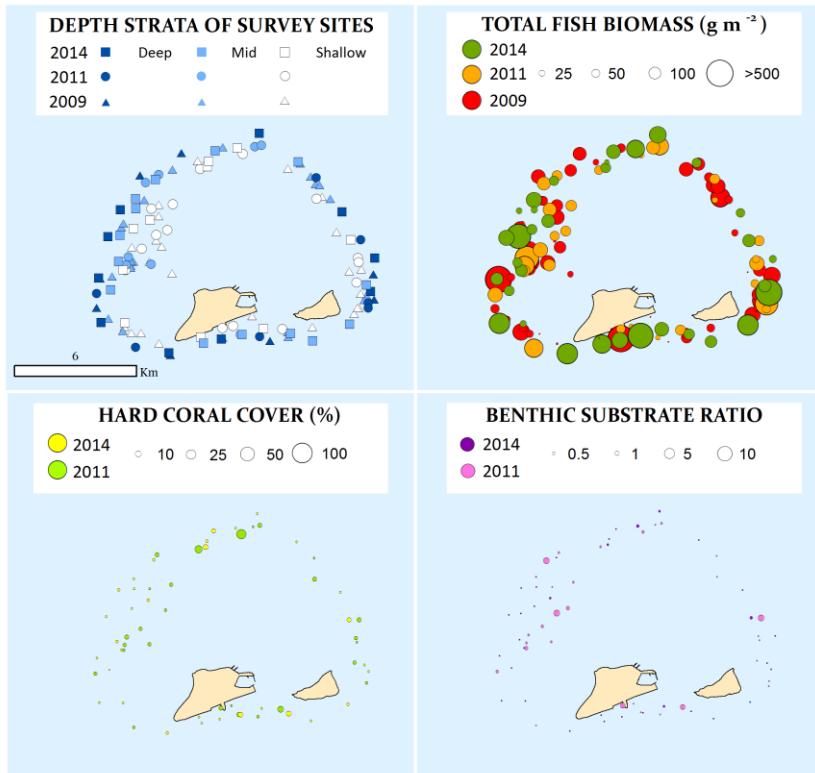

Figure 36 Midway Island site survey data 2009, 2011, and 2014 identified by depth strata (top left). Total fish biomass recorded at each site per year (top right). Hard coral cover (%) assessed by rapid visual assessment (bottom left). Benthic substrate ratio (hard coral plus encrusting algae / turf and macroalgae) (bottom right). This ratio indicates the balance between the benthic components that contribute to reef accretion (coral and crustose coralline algae) compared to fleshy macroalgae and turf algae that compete for space on the reef.

The fore reef habitat was surveyed in 2009 (n =31), 2011 (n=17), and 2014 (n=30).

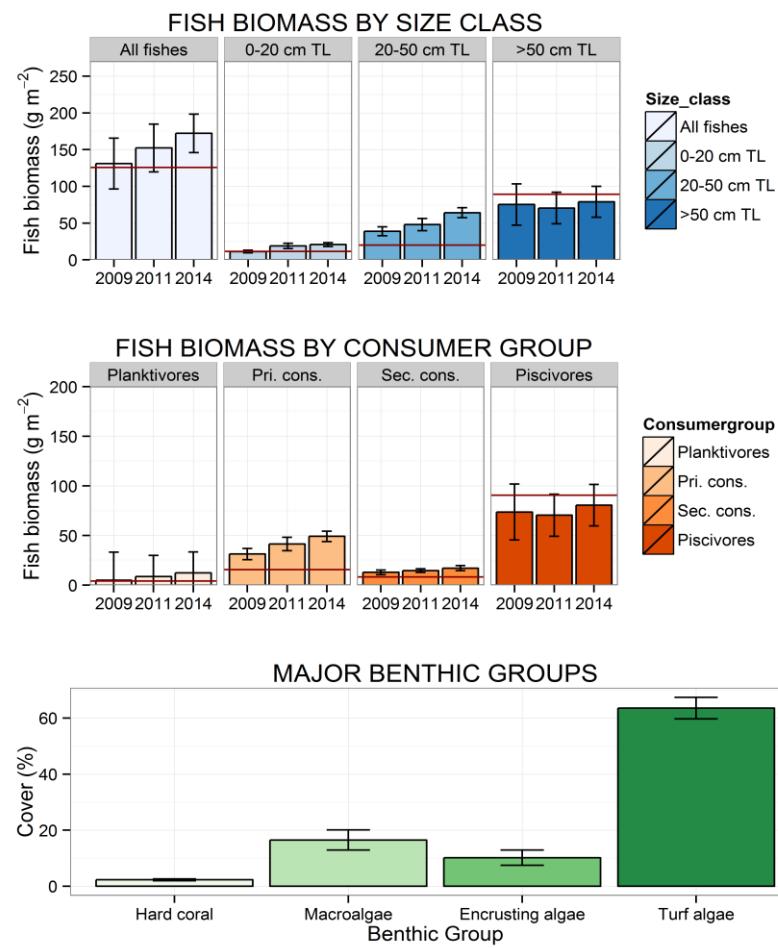

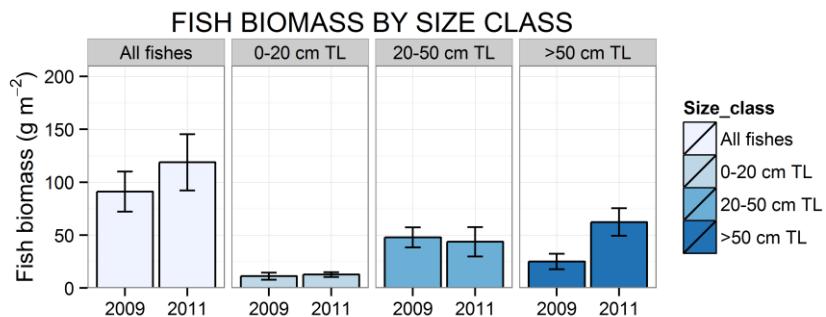

Figure 37 Midway Island fish and benthic plots showing the biomass ( $\text{g m}^{-2} \pm \text{SE}$ ) of fish observed in total and per size class (top) and per consumer group (middle) and the percentage cover ( $\pm \text{SE}$ ) of the benthos for fore reef habitat only. The benthic estimates are pooled across all years. The Northwestern Hawaiian Islands region mean estimates are plotted for reference (red line).

The lagoon habitat was surveyed in 2009 ( $n = 15$ ), and 2014 ( $n = 8$ ).

The backreef habitat was surveyed in 2009 ( $n = 7$ ), 2011 ( $n = 5$ ), and 2014 ( $n = 14$ ).

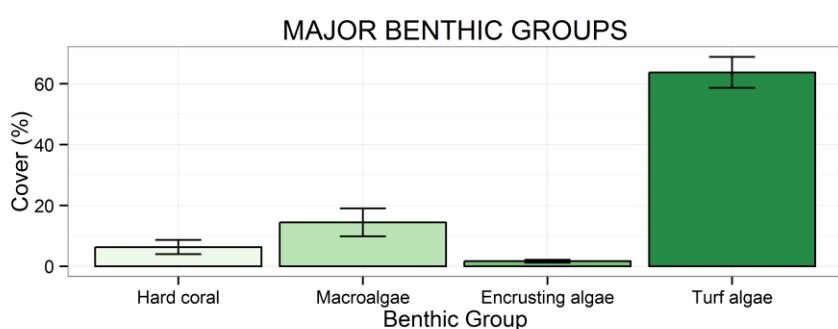

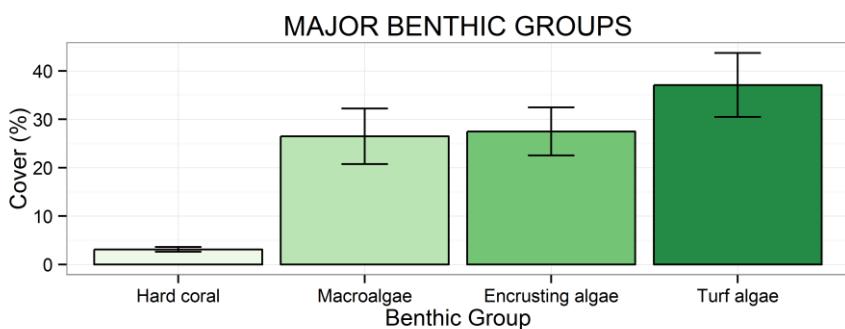

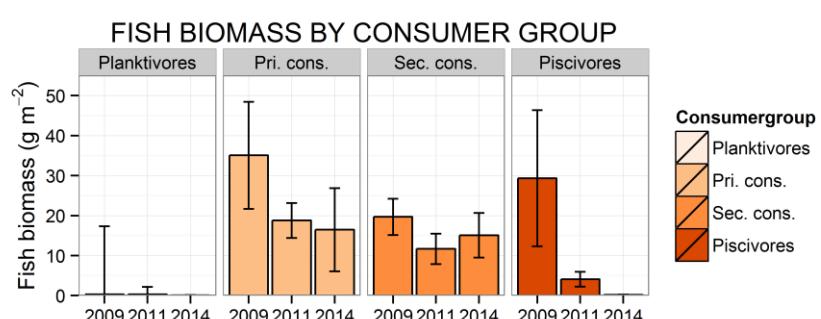

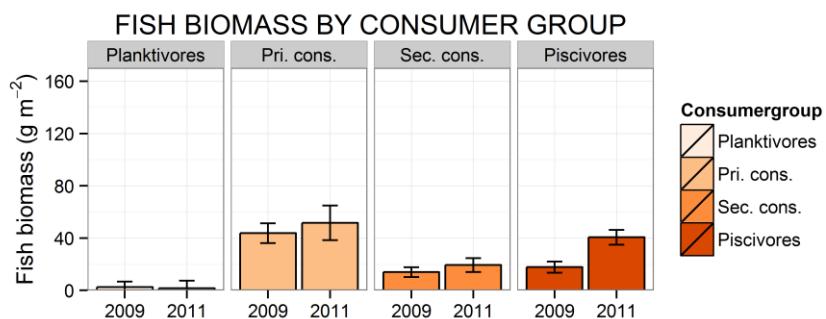

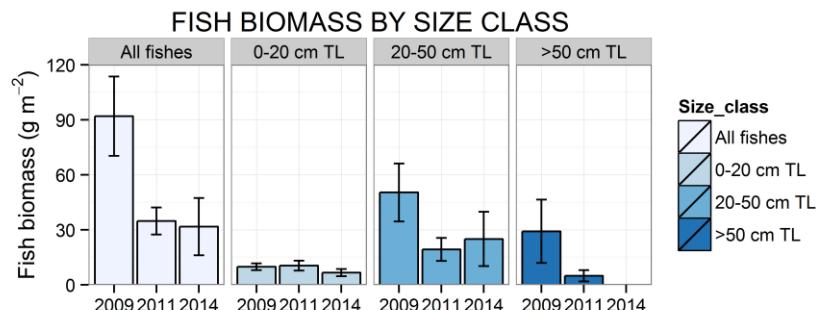

Figure 38 Midway Island fish and benthic plots showing the biomass ( $\text{g m}^{-2} \pm \text{SE}$ ) of fish observed in total and per size class (top) and per consumer group (middle) and the percentage cover ( $\pm \text{SE}$ ) of the benthos for lagoon habitat. The benthic estimates are pooled across all years. The Northwestern Hawaiian Islands region mean lagoon estimates are not plotted due to small sample size.

Figure 39 Midway Island fish and benthic plots showing the biomass ( $\text{g m}^{-2} \pm \text{SE}$ ) of fish observed in total and per size class (top) and per consumer group (middle) and the percentage cover ( $\pm \text{SE}$ ) of the benthos for backreef habitat. The benthic estimates are pooled across all years. The Northwestern Hawaiian Islands region mean backreef estimates are not plotted due to small sample size.

## Pacific Remote Island Areas

### Wake Atoll

Wake Atoll was surveyed in 2009 ( $n=29$ ), 2011 ( $n = 30$ ), and 2014 ( $n=45$ ). Due to its location Wake is surveyed *en route* to the Marianas, therefore the survey years match the Marianas, rather than the PRIA cruise cycle.

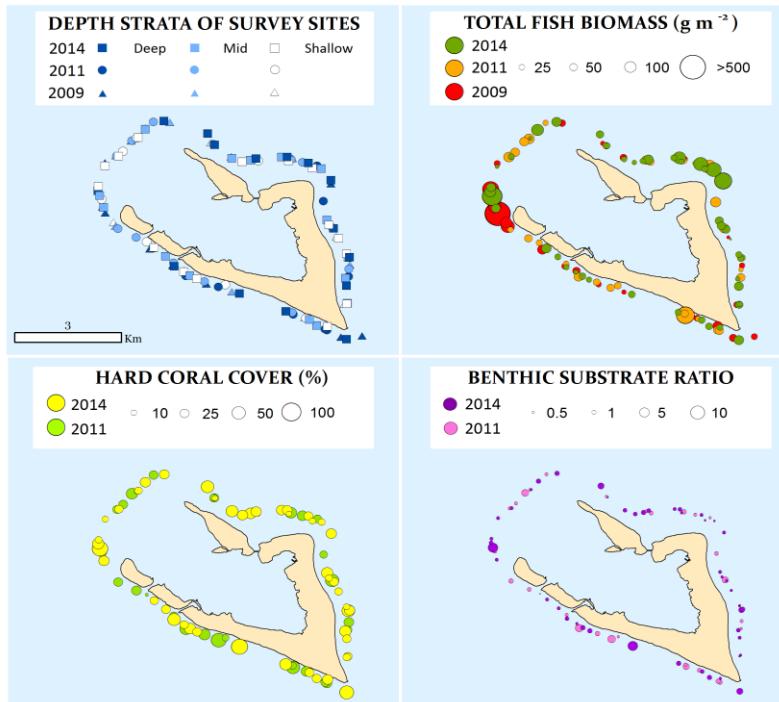

Figure 40 Wake Atoll site survey data 2009, 2011, and 2014 identified by depth strata (top left). Total fish biomass recorded at each site per year (top right). Hard coral cover (%) assessed by rapid visual assessment (bottom left). Benthic substrate ratio (hard coral plus encrusting algae / turf and macroalgae) (bottom right). This ratio indicates the balance between the benthic components that contribute to reef accretion (coral and crustose coralline algae) compared to fleshy macroalgae and turf algae that compete for space on the reef.

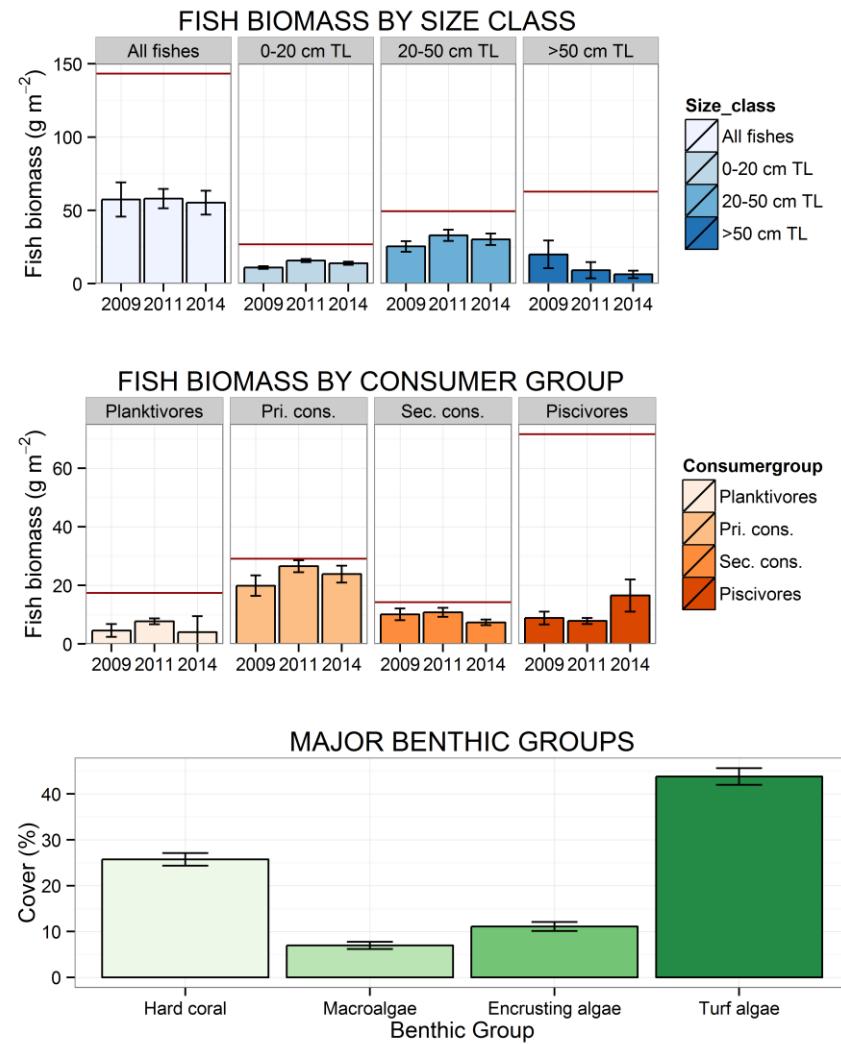

Figure 41 Wake Atoll fish and benthic plots showing the biomass ( $\text{g m}^{-2} \pm \text{SE}$ ) of fish observed in total and per size class (top) and per consumer group (middle) and the percentage cover ( $\pm \text{SE}$ ) of the benthos. The benthic estimates are pooled across all years. The Pacific Remote Island Areas region mean estimates are plotted for reference (red line).

# Publications, information products, and data requests 2014

The following products published in 2014 were either produced using data collected during fish and benthic Pacific RAMP monitoring surveys, or were coauthored by members of the CRED fish team.

# Appendices

## Appendix 1: Pacific RAMP data types collected for the biological theme of the NCRMP

Theme	Indicator	Method	Spatial sampling	Temporal scale
Benthos	Coral demographics and condition: species, abundance, size, bleaching, disease, mortality	Paired 18m coral demographic transects	Stratified random sampling optimized for commercially and ecologically important fish and coral species in shallow (0–30 m) hard bottom areas. Strata include depth, habitat type, and management zone.	Surveys conducted every 3 years, all surveys generally conducted within the same 3-month season.
	Benthic percent cover	Paired 15m photoquadrat transects		
	Benthic key species (presence/absence)	2000 x10m towed-diver survey		
	Rugosity			
Fish	Fish abundance, size, and species	Paired 15-m-diameter stationary point count (SPC) surveys		
	Fish key species (presence/absence)	~2000 x10m <sup>2</sup> towed-diver survey		

Table A1.1 Summary of the benthic and fish data collected (indicators), and the various methods, sampling design and survey cycle of the NCRMP

## Appendix 2: Surveys per region per year and method used

Year	2000	2001	2002	2003	2004	2005	2006	2007	2008	2009	2010	2011	2012	2013	2014
Region							Belt & SPC	Belt & SPC	Belt & SPC						
Method	Belt	Belt	Belt	Belt	Belt	Belt				SPC	SPC	SPC	SPC	SPC	SPC
N. Mariana				42		38		36		135		135			148
S. Mariana				25		34		30		116		219			198
Main HI						73	57		186		184		163	287	
NWHi*	58	18	63	62	57	40	64	155	147	203	118	141	91		89
PRIAs		30	34		48	13	67	12	193	42	179	30	231		45
Am.Samoa			42		58		61		222		241		223		

Table A2.1 The number of sites surveyed per region per year. From 2000–2006 the belt transect method was used to survey coral reef fishes. During the calibration period that took place from 2006–2008, surveys were conducted using both the belt and the stationary point count (SPC) method. The SPC data collected prior to 2009 is not used in this report because sites were not selected based on the randomized depth stratified design (see [Section: Methods](#)). Furthermore, during the methods transition period, sites surveyed at the mid-depth strata in 2009 were the haphazardly selected, fixed sites selected in the previous years. Shallow and deep sites were randomly selected. Here we report all data from 2009 onwards, including the non-randomized mid-depth 2009 sites. In the future, these mid-depth sites should be excluded from any time series analysis.

\*In partnership with NOAA's Papahānaumokuākea Marine National Monument (PMNM) surveys have been conducted in the Northwestern Hawaiian Islands on a more frequent, almost annual basis.

## Appendix 3: Sectors maps

For the majority of islands, the entire island or atoll is stratified by habitat or depth. Guam and the main Hawaiian Islands, however, have an additional level of stratification.

### Guam

Guam is subdivided into sectors based on management status (marine preserve or not) and aspect (East or West): thus there are two open sectors: “Guam Open East” (areas outside of Marine Preserves on east side of Guam); and “Guam Open West”. Grouping of marine preserve sites – i.e. whether to pool all into a single strata ‘Guam Marine Preserve’ or break out at level of some or all individual marine preserves depends on sampling density per year – higher sampling density allows for individual marine preserves to be sectors. In 2014, we pooled MP sites into “Achang MP” (Achang Reef Flat Marine Preserve, due to intensive sampling efforts there); “Marine Preserve” (all other areas within Guam’s Marine Preserve System; (Figure A3.1).

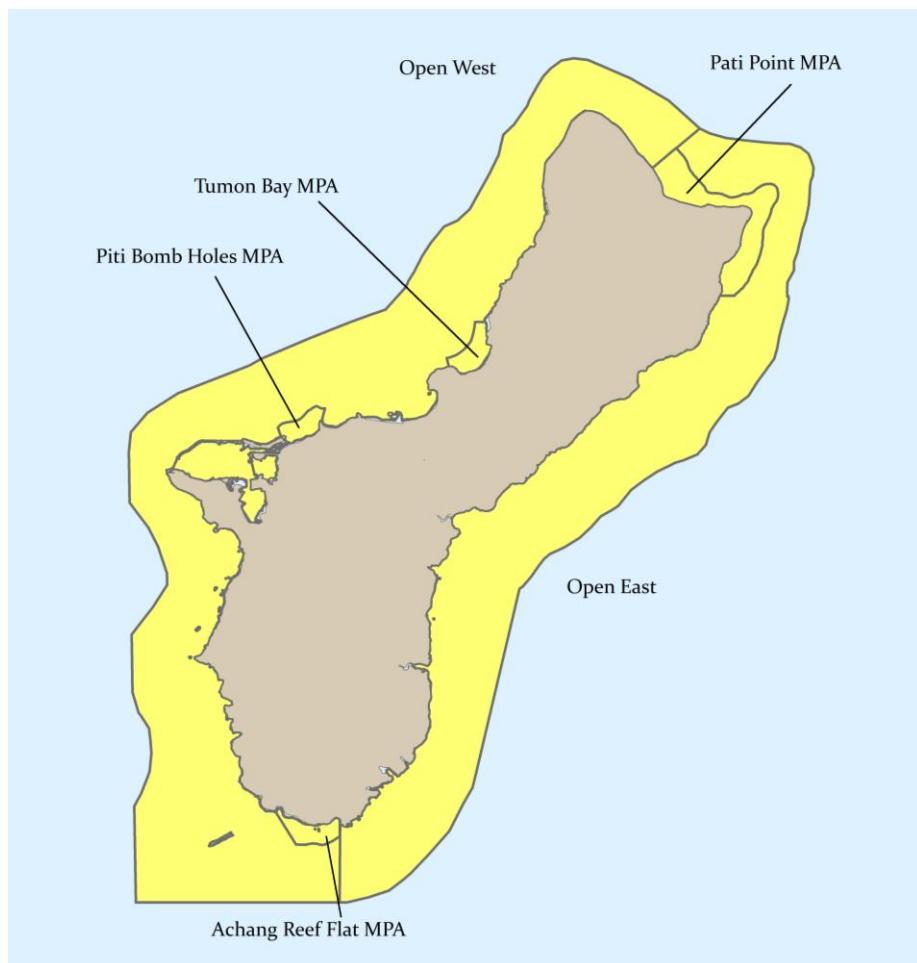

Figure A3.1 Guam sectors. Sampling is stratified by habitat, depth and the additional sectors based on whether areas are inside or outside Achang Reef Flat MP, the pooled Marine Preserve system, and by the East and West side of the island.

## The main Hawaiian Islands

The main Hawaiian Islands are divided into between 2 and 7 sectors per island, with sector boundaries based on broad differences in oceanographic exposure, reef structure, and local human population density (Figure A3.2).

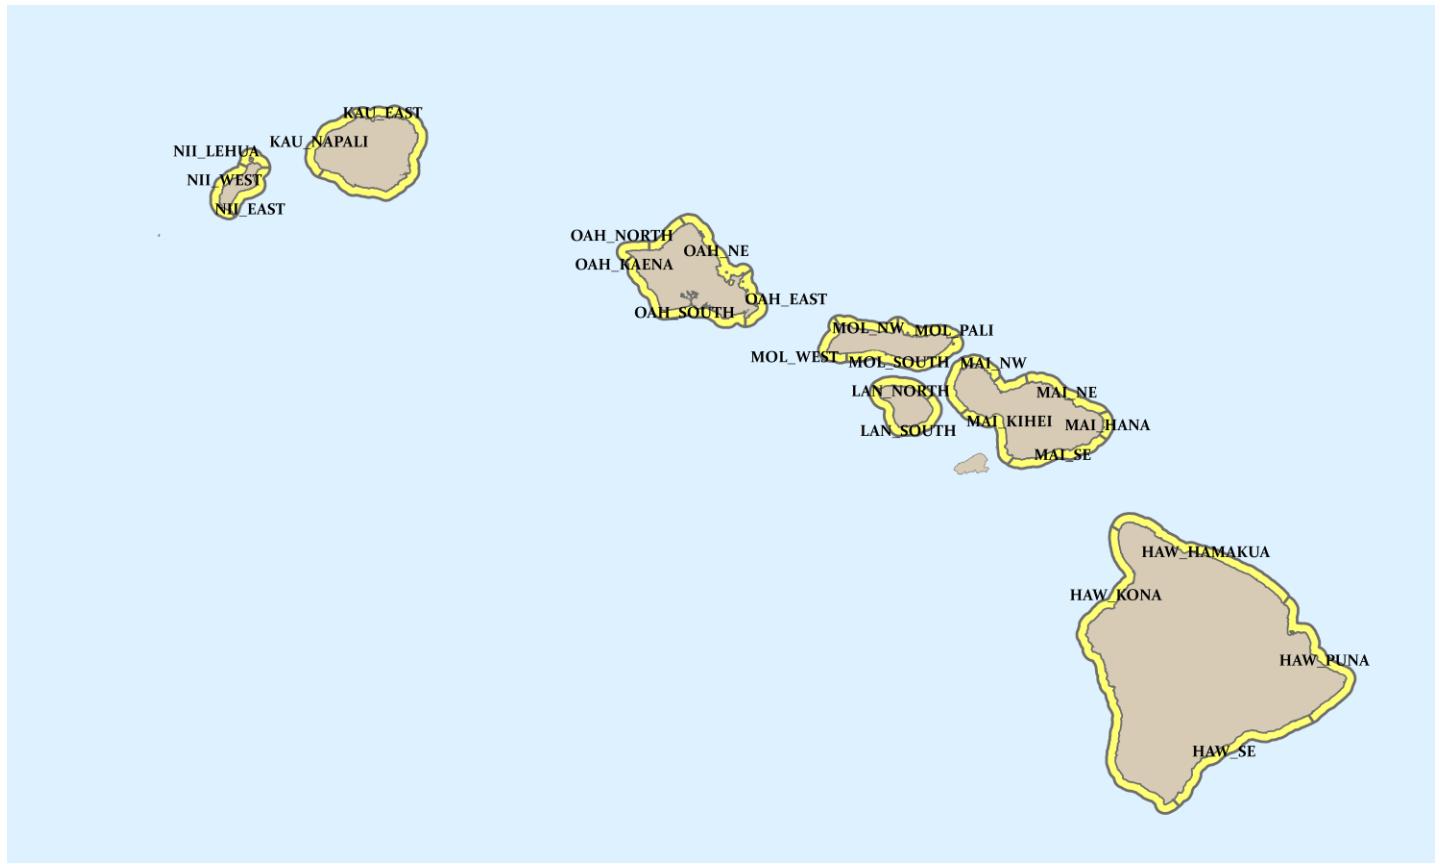

Figure A3.2 The sectors of the main Hawaiian Islands. Sectors are broadly based on wave exposure, habitat complexity and local human population density.

## Appendix 4:Samples per sector and strata in 2014

Table A4.1 The number of sites surveyed per depth strata and the sector used to pool up the data in island level parameter estimates. For most islands, during the site selection process, the sector area from which site locations are randomly drawn are the islands. In some case, such as Guam, islands are broken down into smaller sectors. D = deep (18–30 m), M = mid (6–18 m), S = shallow (0–6 m). Backreef site depths were pooled for analysis.

Year	Region	Island	Sector	Backreef-All	Forereef-D	Forereef-M	Forereef-S
2014	N.MARIAN	AGS	Alamagan	3	5	3

## Appendix 5: Quality control

### Appendix 5.1 Observer training

Typically there are between 4–10 fish divers, or observers, in the field. These observers include a majority of CRED fish team divers, but occasionally partners from local agencies, for example, from the Hawaiian Division of Aquatic Resources, the U.S. Fish and Wildlife Service, and students from the University of Hawai‘i. New observers are trained in both fish identification and the survey technique; this includes a classroom component and in-water training. Prior to each survey cruise, all observers (new and experienced) must meet the minimum pass rate (90%) in a region-specific fish identification test. All observers also take part in in-water training exercises, typically on a monthly basis outside of the cruise season. Generally, the in-water training includes two dives, one to conduct a practice stationary point count (SPC) survey and another size estimation dive. The latter includes divers estimating the sizes of fish models in a mock SPC survey. Diver estimates are then calibrated against the known fish model sizes (for example see Figure A5.1).

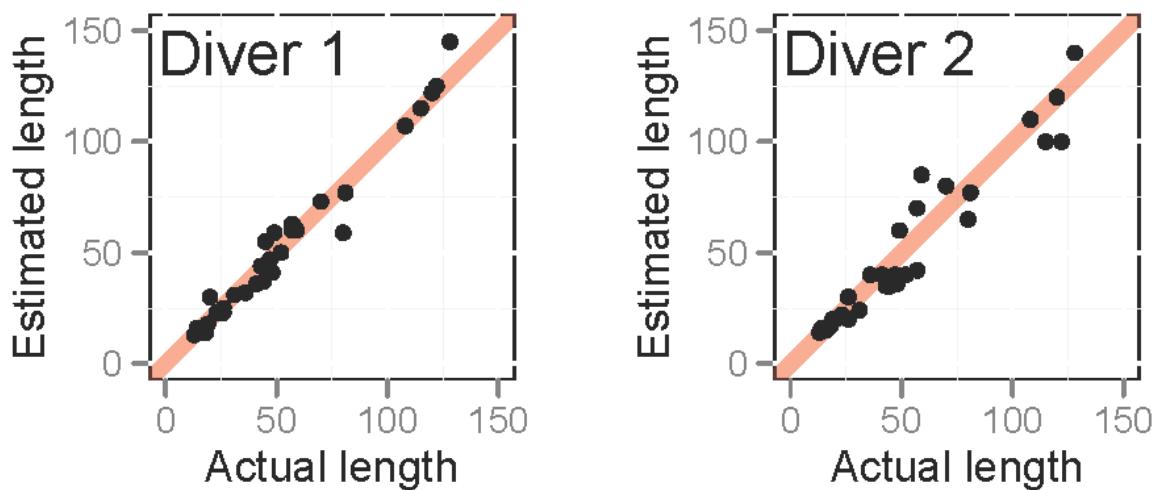

Figure A5.1 Example of size estimation dive training data for two divers. During the size estimation dives, diver accuracy is assessed by divers estimating the size of fish models of known lengths, which are haphazardly distributed throughout a mock SPC cylinder. The closer divers are to the red 1:1 line, the more accurate their estimated sizes.

## Appendix 5.2 Observer cross-comparison

Estimates are compared between dive partner pairs to check for consistency between observers. This can be done for any parameter estimated, but here total fish biomass, species richness (number of unique species counted) and hard coral cover estimates are highlighted, three of the most frequently reported summary metrics from the stationary point count survey data. The difference between the estimates of each diver and those of their dive partner at each site is calculated and referred to here as diver performance. Real differences between dive partners are expected, as divers survey adjacent, not the same cylinder area. However, if there is no consistent bias in the estimates made by a diver, one would expect the median value of their performance to be close to zero i.e. with estimates in half of the counts being higher than their partner's estimates and half of the counts lower than their partner's estimates.

Boxplots of diver performance, therefore, give: 1) a strong but general indication of relative bias, if there is not consistent bias, then the median differences between a single diver and their dive partners will be close to zero and; 2) an indication of how variable each divers' counts are compared to their dive partners – if a particular diver's performance varies extremely widely compared to their dive partners (i.e. several very high and/or several very low counts) that may be an indication of variability in their performance. As dive teams are regularly rotated throughout the course of a survey mission, measures of individual diver's counts reflect their performance relative to the entire pool of other divers participating in those surveys. These boxplots are routinely generated during and after field operations to give divers feedback on their performance relative to that of their colleagues and are summarized here by region (Figure A5.2 northern Mariana Islands 2014, Figure A5.3 southern Mariana Islands 2014, Figure A5.4 Northwestern Hawaiian Islands 2014, Figure A5.5 Pacific Remote Island Areas 2014).

## Northern Mariana Islands 2014

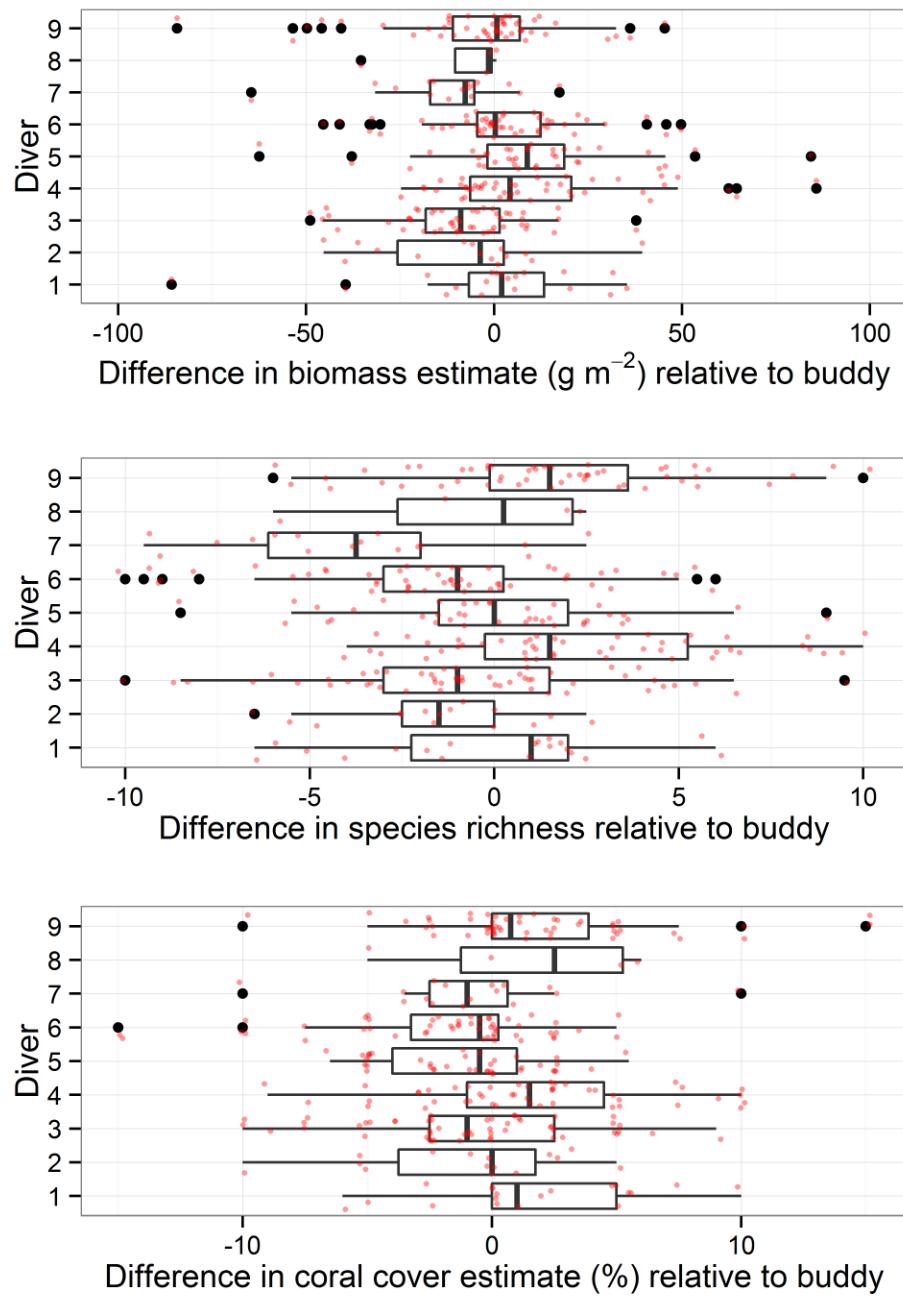

Figure A5.2 Northern Mariana Islands comparison of observer diver vs dive partner estimates for total fish biomass, species richness and hard coral cover during 2014 surveys. The boxplot shows the median difference (thick vertical line) in estimates for each diver, the box represents the location of 50% of the data. Lines extending from each box are 1.5 times the interquartile range which represents approximately 2 standard deviations; points greater than this (outliers) are plotted individually (black dots).

Southern Mariana Islands 2014

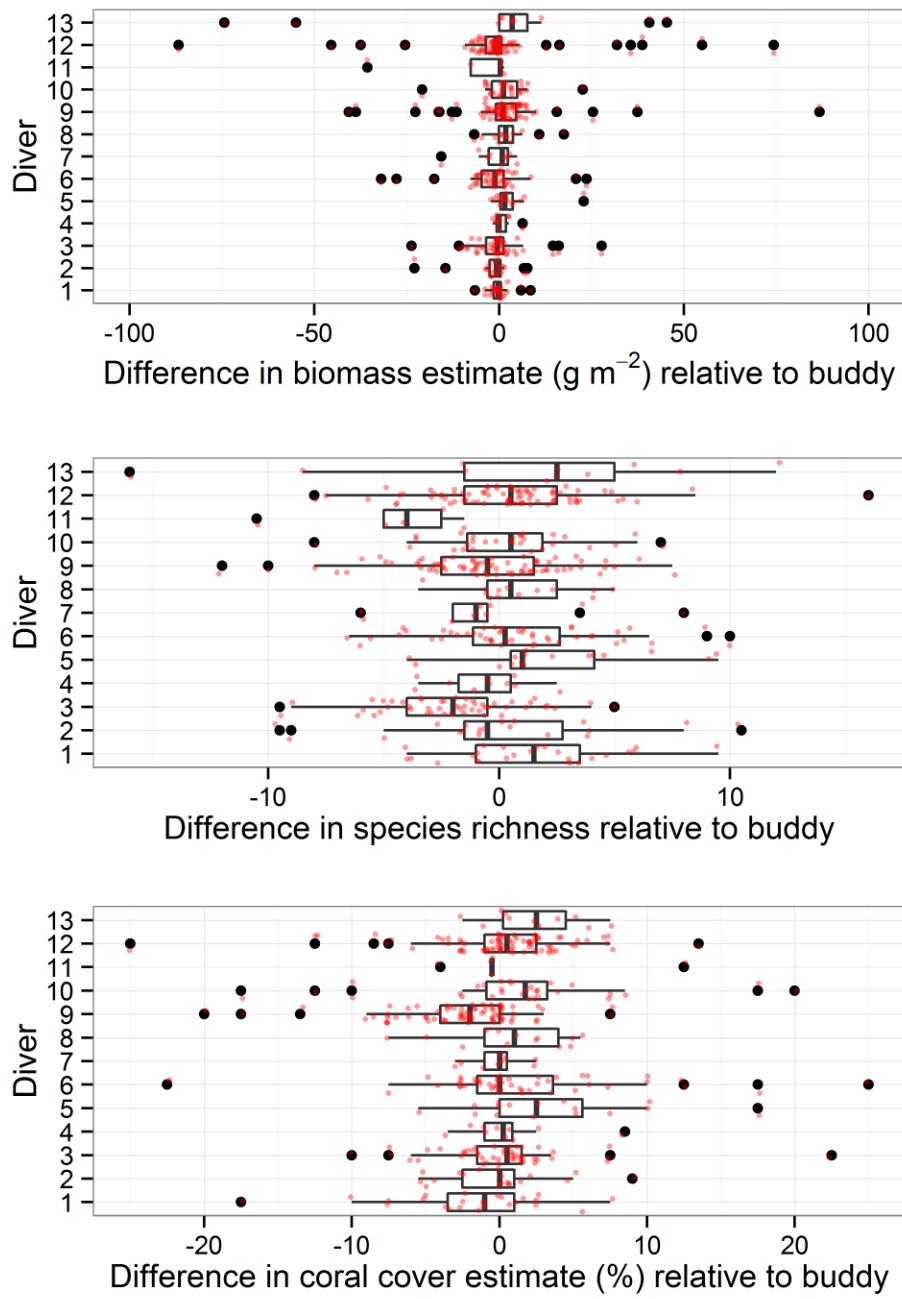

Figure A5.3 Southern Mariana Islands 2014 comparison of observer diver vs diver partner estimates for total fish biomass, species richness and hard coral cover during 2012 surveys. See Figure A5.2 legend for details.

## Northwestern Hawaiian Islands 2014

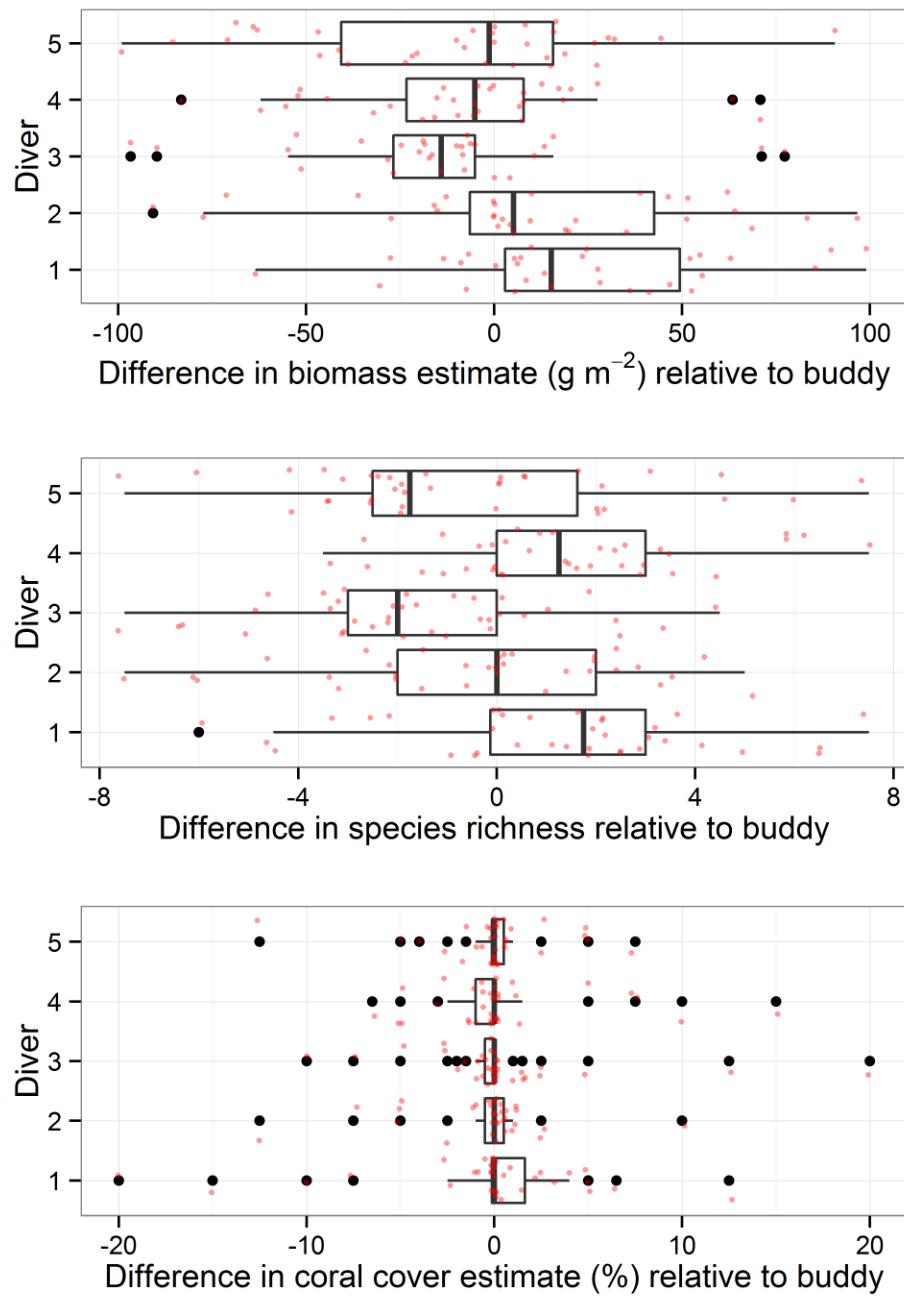

Figure A5.4 Northwestern Hawaiian Islands comparison of observer diver vs dive partner estimates for total fish biomass, species richness and hard coral cover during 2014 surveys. See Figure A5.2 legend for details. Note that the 2014 survey cruise in the NWHI was led by the PMNM. Although methods and design are identical between CRED and PMNM cruises, PMNM cruises involve divers with a wider range of experience levels than is typical for CRED cruises.

Pacific Remote Island Areas 2014

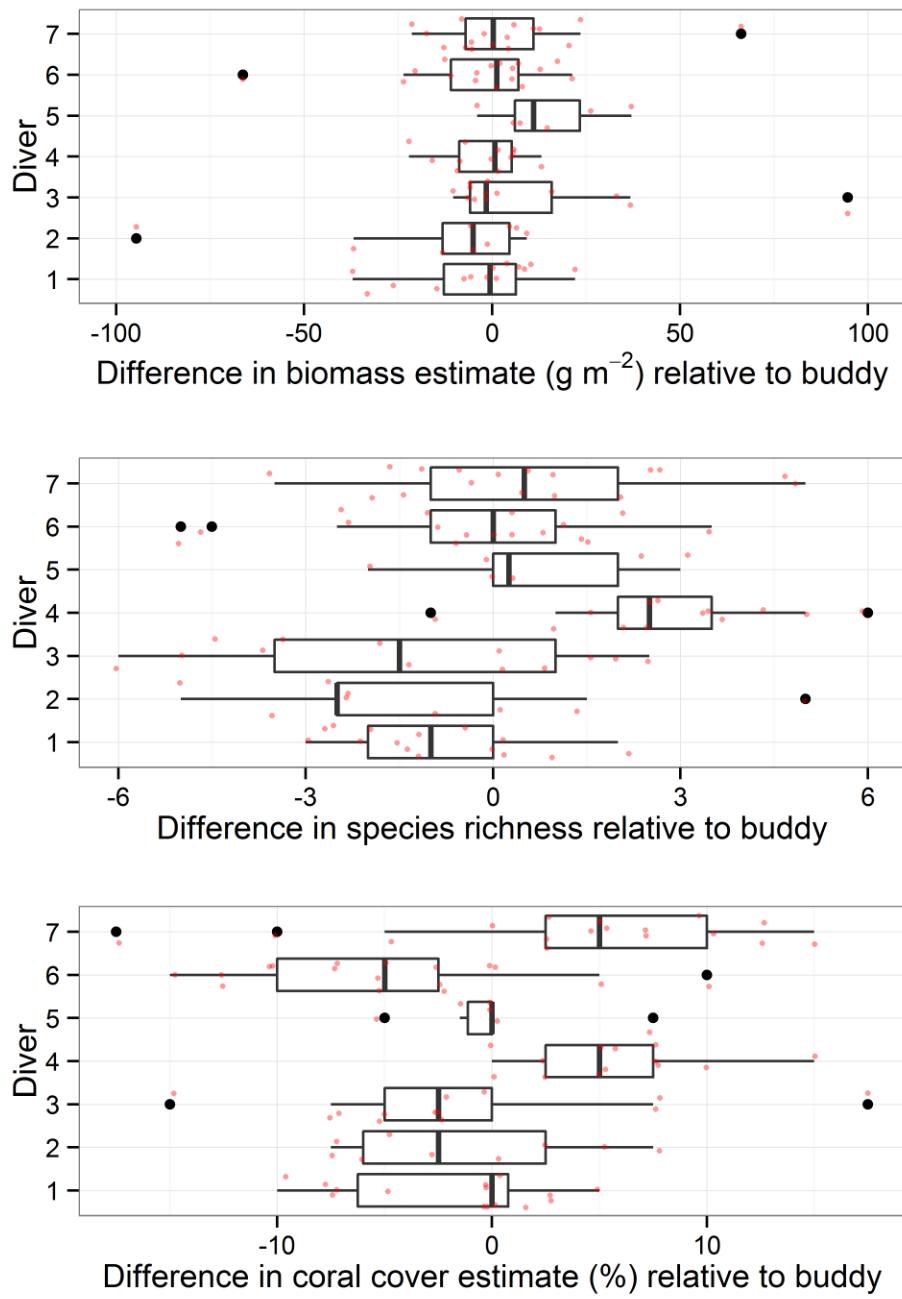

Figure A5.5 Pacific Remote Island Areas comparison of observer diver vs dive partner estimates for total fish biomass, species richness and hard coral cover during 2014 surveys. See Figure A5.2 legend for details.

## Appendix 6: Species list

Table A.6. Species list ordered by abundance within consumer groups, showing length to weight parameters (LWA and LWB) used to calculate biomass per fish based on the estimated individual fish total length (Froese and Pauly 2010 and Kulbicki *et al.* 2005). The conversion factor (Con.factor) is used to translate fish lengths gathered by divers (as total length [TL]) into the length type (TL, fork length, standard length) that the species' length-to-weight parameters were developed for Freq.= number of observations in all regions since 2009 using the stationary point count method. Y indicates whether species have been recorded per region; only regions surveyed in 2014 are displayed.

## Appendix 7: Random stratified sites surveyed at each island per year

Table A.7 The total number of sites surveyed per island (ordered by region) per year under the depth stratified random sampling design, using the stationary point count method to survey the fish assemblage.

Region	Island	2009	2010	2011	2012	2013	2014	Total

## Appendix 8: Site level data

Table A.8 Site level data for regions surveyed in 2014. Displaying region, island, date surveyed, site number, geographic co-ordinates, depth (m), fish biomass by consumer group and size class and percentage hard coral cover. Pri. consumers = primary consumers, sec.consumers = secondary consumers, TL = total length, FFS = French Frigate, FDP = Farallon de Pajaros.

Year	Region	Island	Date	Site	Latitude	Longitude	Depth (m)	Fish biomass ( $\text{g m}^{-2}$ )								Benthos
								Pri. consumer	Sec. consumer	Piscivores	Planktivores	All fishes	0-20 cm TL	20-50 cm TL	>50 cm TL	Hard coral (%)

## Contact us

We are committed to providing ecological monitoring information that is transparent, readily accessible and relevant to the sound management of coral reef resources. For data requests contact: [nmfs.pic.credinfo@noaa.gov](mailto:nmfs.pic.credinfo@noaa.gov)

Users of this data report, we would welcome your comments on how to improve the utility of this document for future versions. Comments or suggestions on the content of this annual data report may be submitted to: [nmfs.pic.credinfo@noaa.gov](mailto:nmfs.pic.credinfo@noaa.gov) with the subject line addressed: For the Attention of the Fish Team Lead.
